here—the only wonder is that on such a fertile soil and in such an environment it did not make more serious ravages. Croydon has, as we know, generally enjoyed the reputation of being particularly careful in its sanitary affairs. Its rural sanitary authority must bestir itself if it is not desirous of losing this distinction, for a clearer case of defective sanitation of a district could not be made out.

THE USE AND ABUSE OF INFANT INSURANCE.

It is not to be expected that a practice so common among the artisan classes as infant insurance should fail to excite some difference of opinion. We are, therefore, prepared to find that our own utterances on this subject are contrary to the views of certain critics. Two of our assertions¹ in particular have been called in question. One is that which relates to the cost of burial as being within the competence of almost all thrifty working people; the other notices a possibly suggestive coincidence in the fact that among 4629 children recently subjected to cruel treatment 1237 were insured. It must not be supposed that in these statements we desire to associate with the principle of such insurances any necessarily pernicious tendency. But, on the other hand, we are by no means sure that they are as essential to the domestic economy of the poor as some have asserted, or so fully justified by their effects as is desirable in the public interest. Homely thrift may not always meet the demands of illness or death, although we believe it can do so much more often than is generally known. Where it cannot, let it be aided by any prudent method which is safe and just, but this, in order to attain its purpose, must, in our view, be regulated with a view to the actual cost of a poor child's funeral, and not by such lavish estimates as ignore that modest estimate; and it will be a matter well worthy of the consideration of the Legislature, when the question of children's insurance again occupies the attention of "the House," whether the limit at present placed by law upon such transactions should not be cut down to a smaller figure than that at which it at present stands.

CHANGES IN THE LIVER IN TYPHOID FEVER.

VERY few observers have drawn attention to the pathological changes occurring in the liver during typhoid fever; nevertheless, marked lesions are frequently found after death. A paper by Dr. J. A. Amyot, detailing the histological appearances thus exhibited, appears in the *Canadian Practitioner* for January of this year. The conclusions arrived at were based upon the examination of the liver in seven cases. Little nodules were found in all the specimens, in some in small numbers and in others in comparatively great numbers. They varied from about one-fortieth to one-fifteenth of the size of the lobules, and were distributed irregularly. Dr. Amyot divided the nodules into two classes, the lymphoid and the necrotic. Neither of them seemed to be of new growth. At first they appeared to be alike, but afterwards became invaded to a greater or lesser extent by lymphoid cells. The nodules were made up of masses of unstained granular protoplasm. In some of these masses the nuclei were still visible, though unstained. Some of the nodules were broken up into several fragments, which stained diffusely. The capillaries of the nodules were filled with granular material. Lymphoid cells were found chiefly in the capillaries, but a few were seen between the hepatic cells. The so-called lymphoid nodules differed from this only in the difficulty with which the formed elements were seen and on account of the great number of lymphoid cells present. They were sharply cut off from the surrounding tissue. Besides these nodules there were present areas of capillary

dilatation, with only the nuclei remaining in the hepatic cells. These areas were of varying size and location, but were generally larger than the nodules before described; they were as a rule circular in form and were not so sharply marked off from the surrounding tissue as the necrotic nodules; they were present in four out of the seven specimens. There was no pigmentation. The other changes in these specimens were nutmeg change, atrophy and pigmentation of the hepatic cells, and dilatation of the capillaries in the intra-lobular vein zone. Fatty degeneration of the cells in the portal vein zone was present in two of the specimens. Beyond some excess of granulation there was no change in the protoplasm of the cells. Dr. Amyot, quoting Dr. Osler, remarks that no definite relation between the typhoid bacilli and the nodules above described has so far been made out.

THE students of King's College have arranged for a concert to be given at the College on Tuesday next, under the patronage of H.R.H. the Duke of Cambridge, the Duke of Westminster, the Bishop of London, the Hon. W. F. D. Smith, and Dr. Wace, on behalf of the funds of King's College Hospital. Mrs. Hutchinson, Miss Gambogi, Madame Haas, Miss Kendall, Madame Anna Lang, Herr von Dulong, Mr. Rumford, Mr. Wolseley, and Mr. Sewell will give their services.

LORD REAY, G.C.S.I., Vice-President of University College, London, will preside at a dinner at the Criterion Restaurant on Wednesday, March 13th, at which Sir John Erichsen, Bart., F.R.S., Sir J. Russell Reynolds, Bart., F.R.S., and Sir John Williams, Bart., M.D., are to be entertained by their colleagues, friends, and pupils. The honorary secretaries, from whom tickets and all information may be obtained, are Dr. Poore, 30, Wimpole-street, W., and Mr. W. A. Meredith, 21, Manchester-square, W.

Pharmacology and Therapeutics.

CHLORAL HYDRATE AND IRON.

SOME recent observations by Mr. Alexander Gunn¹ show that under some circumstances crystals of chloral hydrate are subject to a peculiar yellow discolouration. This affects only the surface of the crystals and seems to be due to the accidental presence of a particle of iron in the stock bottle and to the liberation of free hydrochloric acid. Similar discolouration was easily produced by leaving some ordinary white crystals of chloral hydrate in a test-tube for a week together with a minute fragment of iron.

IODINE ADMINISTERED BY INJECTION.

The injection of a solution of iodine subcutaneously, or into the substance of a muscle, has recently been practised by some Italian surgeons for the treatment of several classes of diseased conditions with apparently much success.² Dr. F. Durante, Clinical Professor of Surgery in Rome, has employed these injections in pulmonary and arthritic affections of a tuberculous character, and more recently Dr. Mennella, a military surgeon, has extended the same treatment to joint affections of a non-tuberculous nature. In two cases of hydrarthrosis of the knee of traumatic origin, where ice, tincture of iodine, blisters, and fixation, together with large doses of iodide of potassium, had been tried for a couple of months without result, peri-articular hypodermic injections of iodine caused the fluid to rapidly disappear. Again, in glandular enlargements both in the neck and in the groin the same treatment gave excellent results. Dr. Mennella subsequently tried iodine injections in cases of syphilitic and grave malarial cachexia, and in anæmia and hydremia in patients recovering from exhausting diseases, also in chloro-anæmia in young girls, and in rickets in

¹ Vide THE LANCET, Jan. 19th, 1895.

² Pharmaceutical Journal, No. 1278, p. 533.
³ La Semaine Médicale, Dec. 26th, 1894.

children. In all these good effects were observed. He then employed the treatment in a tedious case of bronchopneumonia where the cough had persisted for a long time, with insufficient respiratory sounds in the left apex. After a fortnight the patient was able to resume his work. The liquid employed by Dr. Mennella is simply a 1 per cent. solution of metallic iodine in boiled distilled water containing just sufficient iodide of potassium to dissolve the iodine. Of this, fifteen minims are injected once daily. In the case of very anæmic subjects fifteen minims of a 5 or 10 per cent. solution of ammonio citrate of iron may also be injected, either at the same time as the iodine or alternating with it. As a rule, there is but little irritation at the point of puncture, but occasionally the injections have to be suspended for two or three days because of the inflammation produced. Of course, iodism may be produced, but when this occurs it is less severe than when caused by the internal administration of iodide of potassium. The idea of injecting iodine in some of the above classes of cases is not new, though the exact form of solution may be. Mr. Messenger Bradley³ published an account of some cases of glandular tumours which he had successfully treated by injecting tincture of iodine into the substance of the tumour; and previously Dr. Luton⁴ had with excellent results injected a solution of iodic acid in goitre, in indolent adenopathic swellings of the cervical and submaxillary regions, and in a case of osteo-periostitis of a phalanx of the hand. This plan was also adopted in lymphatic tumours with satisfactory results by Dr. Hardman⁵ of Blackpool.

GUAIACOL APPLICATIONS.

In the course of a discussion in the Paris Société de Thérapie on Dec. 12th, 1894,⁶ on the external application of guaiacol in pleuritic effusions and scarlatinal nephritis M. Miron Sigalea, who was one of the originators of this method of treatment, stated that he had never observed any lowering of the temperature, rendering collapse imminent, as reported by some physicians. MM. Grellety and Ferrand, however, declared that caution was very necessary lest a collapsed condition be produced, at all events in patients already very weak and low from the disease. On this subject M. Catillon's warning as to the importance of employing pure guaiacol, which has the property of being completely soluble in glycerine, should be useful. He remarked that whenever a non-crystalline guaiacol is employed no certainty can be felt that it is pure.

THE LANCET

Special Analytical Sanitary Commission

ON THE

MANUFACTURE AND CHARACTERISTICS OF MUNICH LAGER BEER.

GERMAN BEER, more especially the Munich beer, is undoubtedly becoming a very popular beverage in this country. It is not "heady," and is both light and very cool. Those who cannot do sedentary or clerical work after taking the strong and heavy English ales and stout are not inconvenienced by drinking lager beer. It is in every respect an excellent drink for the advocates of true temperance—that is to say, for those who are opposed alike to the intemperance of excessive drinking and the intemperance of total abstinence. German beer ranks side by side with light natural wines, which French legislators now qualify as hygienic drinks. Of all German beers, that which is the most renowned and the most extensively drunk in all parts of the world is undoubtedly the Munich beer. For this reason we have thought it useful to institute a special inquiry with a view of ascertaining how far this preference was justified. It is not to-day, but we might say from time immemorial, that Munich has been renowned for its beer. This reputation, so early acquired, may be due in a measure

to the severity of the Bavarian laws in respect to the making of beer. We find that an official publication dealing with "the common rules concerning the statutes and customs of the Principality of Upper Bavaria and of Lower Bavaria," and bearing the date of 1516, contains the following enactment: "Wheresoever in our towns, markets, and rural districts, it is forbidden to employ other material beyond barley, hops, and water for the making of beer." This law was renewed in an "ordinance of beer," dated 1616. Finally, the law is reaffirmed by an ordinance of April 25th, 1811, and by the law of Nov. 10th, 1861.

Apart from the laws restricting brewers to the use of only malt, hops, and water, there is another legislative reason why Munich beer should be of good quality. A tax has been imposed on malt since the year 1543. Now in the breweries there is a special apparatus, which is sealed and kept under control by Excise officers. The malt passes through a sort of revolving drum; each revolution is recorded mechanically, like the revolutions of a steam engine, and thus a correct account of the amount of malt that has gone through is obtained. The tax varies according to the quality of the barley employed; therefore there is nothing to be gained, so far as the tax is concerned, by using inferior qualities of barley. This malt tax being very high, it pays best to have only the best quality of barley. Then there is the law of May 16th, 1868, which in Article 7, after again repeating that beer shall be made only of hops, malt, and water, adds that it is especially forbidden to use barley that has not been converted into malt, or that is mixed, partly barley, partly malt. Thus the law has brought about the best fundamental conditions for the production of a really wholesome beer; for, not only must beer be made exclusively of malt, hops, and water, but the excellent quality of the malt is ensured. Now that beer is manufactured with the aid of complicated machinery and in enormous quantities, the great object of brewers is to ensure uniformity of quality. For this the same water and the same barley are necessary. One reason of the superiority of Munich beer is the great skill with which the barley is selected. The barley must have a definite amount of albuminous substances so as to produce a good fermentation, and it is not the barleys with the best exteriors that give the best results. On this point it is difficult to lay down a fixed rule, and where only a small quantity of beer is brewed it is possible to watch the effects and modify the procedure accordingly; but when a large quantity of beer is brewed it is more practical to use a barley of such quality as will give a stable result. Better barleys are therefore now employed. It is, however, especially in the details of manufacture that the explanation of the excellence of Munich beer will be found. Therefore, to understand the subject it is necessary to visit throughout a leading brewery. There are thirty breweries at Munich, and as it was impossible to visit all these vast establishments, a selection had to be made, and the directors of the Löwenbräu, which stands first of the large breweries, gave every possible facility for the complete inspection of all the processes they employed in the manufacture of the most popular of German beers.

The process of brewing differs greatly from that generally practised in England, and, as will be seen, it is well calculated to produce a very wholesome beer. It is reckoned that one hectolitre of malt will give a little more than two hectolitres of beer. Water, which weighs four times more than the malt, is first mixed with the malt when cold, and slowly warmed to 12° or 14° R. (60° F.). This done, hot water is pumped on to the mixture till it attains a temperature of 28° R., care being taken to stir actively the whole time, and thus the malt is well distributed throughout the liquid. Of course, this is all done by machinery. Only a portion of this liquid is brought over into a second boiler, and there it is heated to boiling point—that is, 80° R. (212° F.). What remained in the first boiler is no longer stirred, but the portion which has been boiled—it now takes the name of mash—is sent back and mixed with the stagnant part till the two together attain a temperature of 38° R. (120° F.). The same process is again repeated in all three times, till the temperature of the latter is raised to 58° or 60° R. (170° F.). The liquid resulting from this slow heating and mixture of water and malt is what is called wort. It is now placed in a tank, which has a sieve filter at the bottom to retain the malt, while the clear liquid passes to the space underneath. When this filtered liquid, by

⁴ THE LANCET, Sept. 27th, 1875.

⁵ THE LANCET, Oct. 9th, 1875.

⁶ La Semaine Médicale, Dec. 26th, 1894.

the opening of a tap, is allowed to pass away, hot water is poured on the grain that remains above the sieve. This water draws the extract of the grain, and forms at first a very strong wort, which soon gets weaker and weaker. It is so contrived that, when all the worts, weak and strong, are mixed together, the general average of the liquid shall contain 14 per cent. of extract. The wort, after it has been boiled with the hops and filtered, is pumped to the topmost floor of the brewery, where it spreads out in twelve large, shallow, tray-shaped tank-coolers. To further cool the wort it travels down to the cellars through double pipes. The water used for cooling of course soon gets warm, but it is cooled again by being thrown over a large quantity of pipes filled with ammonia. Also, through this sort of cascade four ventilators propel a strong current of air. The whole of the process up to this point takes about twelve hours, and when once the wort has been cooled the fermentation may be allowed to begin.

The first fermentation takes place in large open vats, and lasts from ten to twelve days. It commences at a temperature of 5° R. (43° F.), and is allowed to reach a temperature of 8° R. (50° F.). At this point the heat is checked, and this is done by introducing into the vats tubes and hollow plates, inside which very cold water circulates. Also, the cellars in which the fermentation takes place are kept at a temperature that is only a degree or two above freezing point. When the fermentation is over the beer is at a temperature of 5° or 5½° R. It has then to be reduced to a temperature of 2° R. (36° F.), which is accomplished by passing it through cooling pipes. It may now be placed in casks in which the second fermentation is allowed to take place. For this purpose the bung is not inserted and the temperature of the cellar is not allowed to exceed 1° R. (34° F.). The second fermentation lasts six or more weeks. The rate of the second fermentation is modified according to whether the beer is wanted quickly or not. If the second fermentation has to be checked this is done by putting wood shavings into the cask, which collect the yeast, and, slowly sinking, carry it down to the bottom of the cask, and thus also the beer is clarified. When the second fermentation is finished care must be taken to fill the cask up to the brim so as to allow no place for the gathering of foam or air, and then the bung hole is closed. The beer must stand eight or ten days, so that enough carbonic acid may be generated to render it agreeable to the palate. But as the beer must not be closed up for longer than ten days in large casks, it is generally at this stage put into smaller casks, where it will keep from six to eight weeks in a cellar the temperature of which is not more than 7° R. (46° F.). Thus it comes to this, that the beer should be drunk within six weeks after it has gone through all these processes or put into bottles and "Pasteurised." What is known as the March beer, which is drunk in autumn, has 16 instead of 14 per cent. of extract before fermentation, and therefore keeps longer.

It will be seen from all these details that the great secret of Munich beer may be summed up in the one short word "ice." At the Löwenbräu Brewery there are enormous engines occupied exclusively in compressing air so as to produce cold. In the vaults of the cellars there are tubes in which salt solution reduced by refrigerators at some degrees below zero is made to circulate. The circulation of the air of the cellar, in consequence of the method of cooling, travels in a downward current, and the aqueous vapours it contains on entering condense on these intensely cold tubes. It forms clusters of ice and snow, and the air that enters the cellar is thus at once dried, purified, and cooled. This is the all-important secret for the production of really good nutritious beer, which nevertheless contains very little alcohol. Great cleanliness and a very cold temperature are the fundamental principles. Formerly it was impossible to make beer in the summer. Indeed, even now the smaller brewers only brew in winter, for it is only by the employment of expensive machinery that a cold temperature can be artificially created. On the other hand, a temperature which is the result of mechanical action can be much more precisely regulated. Therefore, both in winter and in summer we find in the cellars of the brewery exactly the same conditions, and thus a beer of fixed quality and excellence is regularly produced.

In respect to the bottled beer, the bottles, after careful cleansing, and after being filled with beer and corked down by a patent air-tight porcelain and rubber stopper, are "Pasteurised." This means the immersion of the bottles

into a tank of water into which steam is discharged so as to bring the heat up to about 160° F., at which temperature the germs of second fermentation are destroyed, and the beer can then be kept an indefinite time and exported even to the hottest climates. It has been thought that the peculiar flavour of Munich beer is due to a special race of yeast employed. No evidence on this head was forthcoming. Professor Louis Aubray, Director der Wissenschaftlichen Station für Brauerei in München, to whom we are indebted for much valuable information and assistance, stated that there were often several races in the yeast of one single brewery. One special sort of yeast might suit one brewery and not another, but there was apparently no connexion established between the flavour of the beer and the form of the yeast. There is, however, a great difference between yeast of high fermentation and rapid action employed in English breweries and the yeast of slow action utilised by the Bavarian brewers.

Such, briefly, are the main features of the manufacture of Munich beer, as it was shown and explained to us at the largest brewery on the Continent.

THE ANALYSIS OF MUNICH BEER AND THE EXAMINATION OF THE MATERIALS USED IN ITS MANUFACTURE.

We have seen what are the salient points of difference between the English and German or Bavarian mode of manufacturing beer, and we may refer to these points for an explanation of the qualities—especially in regard to flavour, alcoholic strength, and the quantity of malt and hop extractives—which sharply distinguish the one from the other. Thus the peculiar qualities—especially the flavour—of Munich beer are doubtless to be ascribed, in a large measure, first to the fermentation being very slow and carefully restricted to a low temperature. Secondly, the employment of sedimentary yeast tends to render the products of a simpler, and doubtless more wholesome, nature than those which are evolved when a more rapid fermentation is allowed to proceed, such as occurs when a comparatively high temperature and top-growing yeast are adopted. Again, the quantity of hops used in the brewing of Munich beer is much less than is employed in this country, while in Bohemia and Bavaria the hops are gathered earlier, so as to exclude much of the narcotic principles which longer growth fosters. Since, as is well known, the constituents of the hop are distinctly narcotic, this, in addition to the decreased percentage of spirit, would account for the comparative absence of drowsy symptoms when Munich beer is drunk, but which so frequently follow the consumption of English beers. A knowledge, then, of the processes which the Munich brewer employs throws considerable light upon the observation that while Munich beer serves admirably to quench thirst, yet it is devoid of those properties of English made beer which have given rise to the proverbial saying that "to drink beer is to think beer." We may next turn our attention to the information derived in the laboratory upon the composition and character of the various materials employed in the preparation of Munich beer and of the finished beer itself. To this end we have obtained samples direct from the Löwenbräu Brewery at Munich of the water, yeast, and malt, as well as the beer; they were all packed in ice in special conveyance on the journey, and were kept in ice until the precise moment of making the analysis. We may discuss these in the order in which they were examined.

It is well known that variations in the mineral constituents of the water used in brewing exert an important influence on the character of the finished beer. Hard and somewhat saline water, for instance, is preferred in the brewing of pale and bitter ales in this country, since it extracts less colouring matter and—what is more important—less albuminous matter or proteid from the malt. It is the latter substances which, when present in excess, are fatal to the prime condition of English brewed ales. Thus in England hard waters are in general use, as is illustrated in the following analysis of a water drawn from the well of a well-known Burton brewery.

Constituents.	Grains per gal.
Sodium chloride	10.12
Calcium, magnesium, and potassium sulphates (permanent hardness)	36.58
Calcium and magnesium carbonates (temporary hardness)	17.21

On the other hand, the Munich brewer uses a softer and practically non-saline water, which extracts a greater and requisite amount of albuminous principles. This is confirmed by the following analysis, made in our Laboratory, of the sample of water used in the Löwenbräu Brewery.

Constituents.	Grains per gal.
Sodium chloride	0.46
Calcium and magnesium sulphates (permanent hardness)	7.21
Calcium and magnesium carbonates (temporary hardness)	8.69

Thus it will be seen that the Burton water is twice as hard as regards temporary hardness and five times as regards permanent hardness, and, in addition, contains a notable amount of common salt, of which the Munich water contains none. It was, further, remarkably free from organic matter and perfectly bright and clear.

It has already been mentioned that a yeast that is formed by a violent or racy fermentation and at a higher temperature, as employed in English brewing, has more active qualities than yeast found at a lower temperature and by slow fermentation. The first spreads itself rapidly over the surface of the fluid and is termed "superficial" yeast, while the second sinks to the bottom of the vessel and there continues its action; it is, therefore, termed "sedimentary" or bottom yeast, and is what is employed in the Munich Löwenbräu Brewery. The important advantage of the use of a yeast growing at a low temperature in brewing is that while the normal functions of the yeast are free to act, yet the same cold discourages the growth of disease ferments, and a healthier beer is ensured. A sample of the Löwenbräu yeast on examination presented the appearance of a firm, clean grey sponge, which, under the microscope, was seen to consist of well-developed and regularly sized cells and to be quite free from foreign matters, and, what is more important, from bacterial forms of life. An excellent fermentation was induced by its use in an experiment we tried with a solution of ordinary cane sugar.

The excellence of the hops grown in Bohemia and Bavaria is well known, where they thrive under conditions eminently suited to the development of those qualities which are essential for the production of sound and wholesome beer. The samples submitted exhaled the peculiar fragrant odour of the oil of hop when gently warmed and pressed, while no evidence was obtained that the dealers in these hops have sought to preserve them by the process of "sulphuring." The agreeable smell, the sweet, characteristic taste, coupled with the crispness and friability of the malt submitted, afford evidence of its quality, while its activity was shown by the readiness with which a cold-water extract of it converted starch paste into dextrin and sugar. Lastly, the analysis of the finished product, the beer itself, gave the following percentage results. Side by side will be found the results of analysis of two average samples, mild and bitter, of English beer. Thus an interesting comparison is established.

Constituents.	English beers.		Löwenbräu beer.
	Mild.	Bitter.	
Alcohol by weight	Per cent. 6.78	Per cent. 5.44	Per cent. 3.55
" volume	8.45	6.78	4.45
Equal to proof spirit	14.81	11.89	7.80
Total malt extractives	6.74	5.42	7.09
Mineral matters	0.43	0.24	0.36
Albuminous matters	0.26	0.16	0.577
Maltose and dextrin	5.77	4.22	6.15

These results are instructive in partly accounting for the differences of physiological effect between English and Munich beer. Thus, in spite of the fact that the Munich beer contains a greater proportion of nutritious malt extractives than even the strongest beer in the above analyses, yet the alcohol is reduced to almost exactly half the quantity contained in the English beer. It is, however, the influence of both hops and alcohol which combine to produce drowsiness and stupor, so that we have at once a complete explanation of the advantages which the consumption of Munich beer affords in this respect. Nor is the reduction of these constituents effected at the expense of the important

alimentary constituents of beer. On the contrary, the percentage of malt extract in Munich beer is slightly in excess of ordinary "mild" English ale. The nutritive value of malt extractives is due in part to dextrine and malt sugars, but the mineral matter, owing to its richness in phosphate, must add largely to the nourishing properties of the beer. Thus the analysis of the mineral matter of Löwenbräu beer furnished the following results (calculated on a hundred pints of the ash):

Phosphoric acid (P_2O_5)	32.00 per cent.
Potash (K_2O)	37.80 "
Silica	9.44 "
Other salts, chiefly carbonates and sulphates of lime and magnesia	20.76 "
	100.00

The ash consists, therefore, for all practical purposes, of the valuable dietetic agent, phosphate of potassium. It follows also that the nutritive matter of beer, including the nitrogenous principles, are in a soluble form, and therefore favourable for easy assimilation and digestion.

The final operations of analysis were devoted to the examination of the beer for hop substitutes and objectionable preservatives. Although by law the use of substitutes is forbidden in Germany, yet we have frequently found objectionable substance—as, for example, salicylic acid in German export beer. It has already been explained, however, that the Löwenbräu beer is preserved by the simple and effectual process of "Pasteurising," which obviates the resort to the use of objectionable antiseptics, while it does not interfere with the taste or condition of the beer to any appreciable extent. As a matter of fact, we found the beer was entirely free from substances of this class, and our search for bitter substitutes was attended also with similarly negative results. In the light of these excellent qualities which our analyses have brought to view, we are justified in regarding the beer as not only genuine, but wholesome.

DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT.

IV.¹

5. Multiple Certificates relating to the same Patient.

THERE are occasions when two or more certificates of notification are sent to the medical officer of health of a district, the several certificates relating to the same case of infectious disease, and in such instances the sanitary authorities concerned have hesitated to pay more than one fee. The Infectious Disease (Notification) Act is quite clear on that point. It states in Section 3, I. (b) that "every practitioner attending on or called in to visit the patient shall forthwith, on becoming aware that the patient is suffering from an infectious disease to which this Act applies, send to the medical officer of health a certificate." Multiple certificates must therefore be paid for, if they are sent in, where two or more practitioners are "attending on or called in to visit the patient." The only doubt that can remain is as to the meaning of the words "attending on or called in to visit." These words have never received any legal interpretation, and the Local Government Board have announced that they are not empowered to give an authoritative interpretation of Acts of Parliament. But whilst they very naturally take this attitude, they added as follows in a letter to the clerk to the Uppingham rural sanitary authority on Dec. 29th, 1890: "They may, however, state generally that they are disposed to think that a practitioner who sees a patient, not as his medical adviser, but for some purpose unconnected with his treatment, cannot be regarded as [in the words of Section 3, I. (b) of the Act] 'attending on or called in to visit the patient'; and he is, therefore, not required to certify or entitled to be paid for a certificate under the Act. If, however, two practitioners are in actual attendance on or

¹ Parts I., II., and III. were published in THE LANCET of Jan. 19th, Jan. 26th, and Feb. 9th, 1895, respectively.

are called in to visit a patient, whether at the same period or successively, and their attendance or visiting is connected with the medical treatment of the patient, both are, in strict law, required to send certificates of notification, and these must be duly paid for by the sanitary authority." Also, in another letter at about the same date, the Local Government Board wrote: "If, as a matter of fact, a patient is suffering from a notifiable disease when a medical practitioner is called in to attend on such patient, the fact that a notification in respect of the case has been given by a previous medical attendant (whether such attendant is medical officer of health or not) does not dispense the second medical practitioner from the obligation of certifying."

Beyond the principles here indicated we do not feel that we can usefully lay down any rule on this subject, but we are of opinion that there are cases in which it is possible to put too great a strain upon the actual words of the section. Thus, where a medical practitioner who is in attendance on a case sends on occasion one or more qualified assistants to pay odd visits on his behalf he may hesitate to authorise the issue by them of new certificates of notification.

6. Notification by Medical Practitioner as well as by Head of Family.

It will be remembered that under Section 3, I. (a) of the Act the head of the family or other responsible person is obliged to notify to the medical officer of health the existence of cases of the specified infectious diseases; and that under (b) of the same section a similar duty devolves on the medical practitioner in attendance. This is, in fact, the system of dual notification. But as a dual system it is in one sense a dead letter, for proceedings are now rarely if ever taken to enforce certificates from the heads of households in cases where a medical practitioner is called in and notifies the disease. But there are instances of mild infectious disease in which the head of the house does notify, and it is only later, when graver symptoms supervene, that a medical practitioner is called in. Whatever the period at which the medical practitioner is called in and becomes aware of the fact that the disease is a notifiable one, it is his duty forthwith to send in a certificate of notification, and this notwithstanding the fact that he knows that a prior certificate has already been transmitted to the medical officer of health by the parent or head of the house. That this is also the view of the Local Government Board will be seen from the following extract addressed by that body to the town clerk of Hoxton on Feb. 6th, 1891: "As regards the general question, I am to state that it does not appear to the Board that the fact that a notice has been given under Subsection I. (a) of the Act relieves a medical practitioner from his obligation to give a notice under Subsection I. (b) of the Act, but that the Board cannot undertake to express any opinion as to the general expediency of enforcing such obligation under the circumstances mentioned in your letter."

7. Certificates of Notification by Medical Officers of Health.

In dealing with the subject of "multiple certificates relating to the same patient," we incidentally referred to a precedent which shows that a medical officer of health, when in attendance on cases of notifiable infectious disease, is bound, like any other practitioner, to draw up a notification certificate as to the case, and is equally entitled with any other practitioner to the fee for so doing. Some authorities have contended that they ought not to have to pay the notification fees to medical officers of health, but the Act makes no distinction between medical officers of health and other medical practitioners, and the letter from the Local Government Board which we have quoted shows that where a medical officer of health is "attending on or called in to visit the patient" he is entitled to his fee just as if he were an ordinary medical practitioner. The visit should, however,

be definitely one of attendance on the patient and not one of inspection as health officer.

We do not pretend that in this series of articles dealing with Difficulties arising under the Infectious Disease (Notification) Act we have exhausted all the points as to which doubt has arisen or may arise. There must remain a number of difficulties which can only be solved by reference to the actual circumstances under which they have arisen, and there are others which, though they have general application, occur at such rare intervals that it hardly becomes necessary to deal with them in any general articles. But we trust that we have been able to supply information that will serve as a guide both to medical officers of health and to medical practitioners generally, and that the precedents we have quoted may save misunderstandings and difficulties that might otherwise arise. We conclude by once more stating that many difficulties would be avoided between the medical officer of health and the regular medical practitioner if the courtesies which are deemed essential in cases of consultation and other joint action between medical practitioners were always studiously observed on both sides in all matters relating to the notification of infectious diseases. That this view is strongly taken at Whitehall has already been made evident; it is one which we cordially endorse, and hence we conclude by again reminding all concerned that in the interpretation of the duties devolving on one and another medical practitioner under the Act in question it must be taken for granted that "the customs that usually govern the relations of medical practitioners to each other" will in all cases be observed. This being done, the remaining difficulties will be purely technical and will in no way involve professional considerations.

THE UNIVERSITY RIOTS IN ITALY.

HIS EXCELLENCY DR. BACCELLI, Minister of Public Instruction, has closed the University of Naples for the remainder of the academic year. This step is a summary one, but, on due consideration of the facts, justifiably so. A number of students having failed to pass their examinations in July, and having either declined to come up again or failed a second time, in the so-called "sessione di riparazione" conceded them in November, have insisted on a third opportunity being afforded them in March. The inconvenience of the "sessione primavera" (spring session) thus demanded has already, on the occasions when it has been granted, proved intolerable, and the Senatus Academicus refuses to be coerced into making it an "institution." Other universities, equally with that of Naples, have voted it a nuisance, and, acting on the representations of the collective academic mind of Italy, Dr. Baccelli has suppressed all such "sessioni straordinarie," or supplementary sessions *simpliciter*. A number of the students in each seat of learning, but very far from a majority of them, have protested at this interference with their "rights." Their indignation has taken the form of violent interference with the business of the classes; professors have been insulted in their chairs and even outside the University precincts; and, in short, the insubordination in nearly all the faculties has been such that a period of absolute suspension of academic work has been judged necessary. That period may be long or short, according to circumstances. At Bologna, for instance, after a brief interval "for deferrescence" the University was reopened. But in Naples, owing, doubtless, to the more excitable southern blood, a longer suspension has been found imperative, and, as already stated, the classes have been closed for the rest of the current *annus academicus*. In taking this step Dr. Baccelli has the approval of nearly all the heads of the educational world. Only in a few organs of very advanced opinion has there been the slightest note of censure. Why, it is asked, is the bad conduct of a section of the students to be visited with punishment by which all are the sufferers? A wise instinct has guided Dr. Baccelli in the step he has taken. It is this: the Universities must be removed from

State control and made, as in their bright mediæval foretime, autonomous. In other words, the "sensus communis" of the whole University body, including students as well as teachers, must give tone and law to its life and working. So long as that power was retained the well-conducted majority of the students made short work of their riotous fellows, and, in concert with the professorial or governing body, purged their ranks of the rowdy element. Far otherwise is it with the Italian universities as they have since degenerated. Under State control they are now dominated by political ideas, and no student, however insubordinate, is without the consciousness that he can find some friend in the Chamber of Deputies to make an interpellation in his behalf. Successive Ministers of Public Instruction, in fact, have, especially of late years, been hampered in every way by the power possessed by undergraduate organisation to get the ear of Parliament and make their grievances or claims "State questions." Under this system students are almost invited to become politicians, at an age, however, when their one and only concern should be their preparation for professional life. Concentration of thought and work is thus made next to impossible for all but those who have the moral strength to resist the surrounding contagion. All this Dr. Baccelli aspires to put an end to by a return to the condition of things which prevailed at Bologna, Pisa, Padua, and such like centres of academic culture at, and immediately after, the Renaissance. Let there be two distinct "spheres of influence" dominating the student's career. Let there be the examination for graduation, in which only the University shall have a voice. Secondary to that, let there be the examination by the State giving the right to practice. The former grants the *jus docendi*, the latter the *exercere*. Full liberty to teach it is for the University to confer; but when it comes to bringing that teaching *en rapport* with the public—in other words, when the practitioner is brought into relation with the citizen—let the State see that the public have a duly qualified functionary, be he medical man or lawyer or engineer. By that time the University shall have done its work. The body of graduates, long past the stage at which youthful insubordination occurs, will, with a view to professional practice, be subjected to government examiners, who shall migrate from one university to another, and grant qualifications impartially and judiciously only after due cognisance of fitness has been taken. Such is Dr. Baccelli's ideal embodied in the rubric, "Torniamo alle antiche tradizioni!" (let us return to the old traditions); and when his Bill, already formed, shall have passed into law we hope to witness a salutary reform in Italian academic life, under which such riots as have lately discredited it will become impossible, and such Draconian measures as that just applied to Naples a thing of the past.

SANITATION IN MASSACHUSETTS.

THE twenty-fifth annual report of the State Board of Health of Massachusetts, which refers to the year 1893, is a production of no mean size, and the subject matter of which it treats is dealt with in a thoroughly scientific spirit. The volume comprises 784 pages, exclusive of an excellent index, and amongst its valuable contents may be mentioned exhaustive reports on Water-supply and Sewerage, the Analysis and Filtration of Water, and an elaborate report on Infectious Disease Hospitals. The volume also contains an interesting account of a series of experiments made by Dr. Thomas Drown, chemist to the Board, on the Amount and Character of Organic Matter in Soils and its Bearing on the Storage of Water in Reservoirs. These investigations were carried on more especially in reference to the proposed storage reservoir for the city of Boston, as it was deemed expedient prior to forming the reservoir to obtain a thorough knowledge of the character of the soil so as to be in a position to determine how much soil it would be necessary to remove in order to procure a clean bottom and sides free from organic matter. The results obtained were, as was to be expected, somewhat irregular, but it was found generally that there was a rapid diminution in the amount of organic matter below a depth of nine to eleven inches, and at a depth of three feet the

amount of organic matter was, as a rule, below 1 per cent. In order to render the observations more complete, samples of the soil were treated with water and the filtrates from the solution analysed. The watershed from which the several samples were taken was but sparsely populated, and the organic matter present mainly of vegetable origin. As a result of a very thorough examination of the effect of water upon the soils experimented with, Dr. Drown has provisionally fixed 1.5 to 2 per cent. of organic matter, as determined by the loss on ignition of the sample dried at 100° C., as the permissible limit of organic matter that may be allowed to remain on the bottom and sides of a reservoir. It is not possible for us here to deal in any way exhaustively with the Massachusetts report, but we may say that it does honour to those who compiled it, and we can conscientiously commend it to the notice of all students of sanitary science. There is one special feature which distinguishes this as well as all the later Massachusetts reports, and that is the completeness with which the writers deal with the statistical side of all such subjects which can be approached from a statistical standpoint. The notification of infectious disease was started at an early date in Massachusetts; indeed, it appears from the report before us that as far back as 1792 householders were required to report cases of dangerous infectious disease to the local authority, while in 1827 dual notification came into operation. An Act of 1893 has specified the diseases "dangerous to the public health," and these include measles, yellow fever, cerebro-spinal meningitis, hydrophobia, malignant pustule, leprosy, and trichinosis, in addition to most of the diseases required by our own Notification Act to be notified. We observe, however, that erysipelas and puerperal fever are not included among the diseases "dangerous to the public health." The report upon infectious disease hospitals, to which we have already referred, was compiled by Dr. S. W. Abbott, Secretary to the Board of Health, owing to oft-repeated demands on the part of local authorities for information upon the subject. Dr. Abbott points out how the increasing tendency of the population to congregate in cities favours the spread of infectious disease, and he shows that in 1840 the urban population of Massachusetts was but 27.1 per cent. of the population of the State, while in 1880 it was 58.4 per cent., and in 1890 69.9 per cent. As an illustration of the relation of this tendency to the mortality and in all probability to the prevalence of infectious disease the following very interesting table is given. The term "Dense" refers to districts where there is less than one acre to each inhabitant, "Medium" to those having more than one but less than four to each inhabitant, and where there are over four acres to each person the term "Sparse" is used.

Mortality from Eight Principal Infectious and Destructive Diseases in Dense, Medium, and Sparsely Settled Districts in Massachusetts, that of Dense Districts being taken as 1000.

	Mortality from							
	All causes.	Measles.	Scarlet fever.	Diphtheria and croup.	Small-pox.	Cholera infantum.	Consumption.	Typhoid fever.
Dense...	1000	1000	1000	1000	1000	1000	1000	1000
Medium ...	825	517	818	780	332	898	810	1109
Sparse ...	760	445	587	634	149	639	727	1175

It will be seen that, with the exception of typhoid fever, there appears a direct relation between density of population and mortality. Dr. Abbott, in dwelling on the advantages of hospital accommodation, points out that where it obtains, the ordinary duties of the household, attendance at school, and the support of the family by the wage-earner can be carried on without disturbance. During the twenty years 1871-1890 the deaths from measles, scarlet fever, diphtheria, croup, and typhoid fever amounted altogether to 74,597; and Dr. Abbott remarks, in regard to these figures, that if the usually observed case mortality of the several diseases was maintained there would have been some 700,000 cases of these diseases during the twenty years; and he considers that, had proper isolation provision been in existence from 1871, a very material proportion of this illness and mortality

might have been prevented. In dealing with hospital construction and management, Dr. Abbott quotes largely from Dr. Thorne Thorne's standard work on the "Use and Influence of Hospitals for Infectious Disease," and it is impossible to read without a feeling of national satisfaction that "hospitals for infectious disease have reached their highest type of development in England." In the report before us plans of pavilions both of the Boston and Cambridge infectious disease hospitals are given. In the former case the arrangement differs materially from those usually found in the more modern fever hospitals in England, and in both cases there are no annexes for cutting off aerially the waterclosets, &c., from the wards. In an appendix to his report Dr. Abbott reviews the practices of different countries in regard to hospital provision, and his report generally serves in an excellent manner the purposes for which it was intended.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on the 7th inst., the President, Mr. J. W. Hulke, F.R.S., being in the chair.

The Council approved the following resolution, which had been adopted by the Court of Examiners on Jan. 23rd, 1895, in consequence of having been called upon by the Council to take into consideration the arrangements for admitting visitors to the examinations:—

"The Court of Examiners, having considered the question of the admission of visitors to the final examination for the Fellowship, are of opinion that for the present it will be sufficient if a notice is handed to each visitor on his arrival, in the following terms—namely, 'Visitors are requested not to approach too closely to the candidates while the examinations are in progress, and to refrain from examining patients in close proximity to the examiners.'"

Mr. J. McCarthy and Mr. Edmund Owen were elected members of the Court of Examiners' section of the Board of Examiners in Dental Surgery.

The Council proceeded to the further consideration of the resolution carried at the meeting of Fellows on Jan. 3rd requesting the appointment of a conjoint committee, and resolved: "In accordance with the opinion of the legal adviser of the College the Council do not deem it expedient to accede to the resolution passed at the meeting of the Fellows held on Jan. 3rd."

It was further resolved: "That a committee of the Council be appointed to receive deputations from the Fellows of the College upon the subject of the resolution of the meeting of Fellows of Jan. 3rd last and to report thereon to the Council." Copies of these resolutions were directed to be sent to the mover (Mr. W. H. Bennett) and the seconder (Mr. T. Holmes) of the resolution at the meeting of Fellows.

A letter was read, dated Jan. 30th, from Mr. W. G. Dickinson requesting by desire of the committee of the "Society of Members of the Royal College of Surgeons of England," that the following resolution might be laid before the Council—viz.:

"That in the event of the Council of the College consenting to form a joint committee, composed of Members of their own body and of that of the Fellows, to consider the desirability of applying for a new Charter they are hereby requested to add some representatives of the Members to the same committee."

In reply, the Council directed that copies of the two resolutions just passed should be sent to Mr. Dickinson.

A further communication was read from the Committee of the Society of Members, giving the reasons of the Society for opposing before the Home Secretary the proposed alterations in the bylaws.

The Council left it to the President to determine whether a meeting of the Council should be held in March. The date of the quarterly meeting in April was fixed for Thursday, the 4th.

WE learn that the Eighth Universal Cookery and Food Exhibition is to be held at the Portman Rooms, Baker-street, from May 7th to 10th inclusive. Cookery competitors will be held and £200 awarded in special prizes as well as medals and diplomas, while half the profits of the exhibition will be devoted to the providing of meals for poor children.

ST. THOMAS'S HOSPITAL.

A MEETING in aid of the special appeal fund for the purpose of opening the closed wards in St. Thomas's Hospital was held in the Egyptian Hall of the Mansion House, London, on Wednesday, Feb. 13th. In the absence of the Lord Mayor, Sir Joseph Renals, his predecessor, Sir Stuart Knill, K.G., presided, and was supported by H.R.H. the Duke of Connaught, president of the hospital. Amongst those present were the Earl of Leven and Melville, the Bishop of Southwark, Mr. Alderman and Sheriff Samuel, Mr. Sheriff Hand, Sir William MacCormac, Sir Henry Doulton (senior almoner of the hospital), the Rev. Newman Hall, D.D., the Rev. David MacEwan, Mr. A. O. MacKellar (senior surgeon to the hospital), Dr. J. F. Payne, Mr. F. A. Bevan, and the treasurer, Mr. J. G. Wainwright. Letters of apology were read from the Archbishop of Canterbury who referred to the growing population of South London and its dependence upon St. Thomas's Hospital for medical aid, which day by day grew more important, the Bishop of Rochester, Duke of Rutland, Lord Selborne, Lord Rothschild, Duke of Devonshire, and Sir Sydney Waterlow. A sympathetic letter was also read from Miss Nightingale, in which she called attention to the moral effect of residence in the wards of St. Thomas's Hospital upon a patient's life.

Sir STUART KNILL, in calling upon his Royal Highness the Duke of Connaught to propose the first resolution, said the citizens of London looked upon St. Thomas's Hospital as essentially their own institution, and it was their duty to take the initiative in commencing to replace that hospital in its proper position. The wards were not closed through bad management, but through the falling of the hospital funds from the great agricultural depression.

The Duke of CONNAUGHT then moved: "That this meeting has heard with sincere regret that notwithstanding the large increase in the population of South London, and the consequent greater demand for hospital treatment, there are several wards in St. Thomas's Hospital lying empty and unused owing to the income of the charity not proving sufficient to maintain a greater number of beds than those now in use (436)." In supporting his motion his Highness referred to the appeal that he had already addressed to the public and hoped they would believe that it was thoroughly genuine, thoroughly open, and contained all the secrets connected with this important hospital. He referred to the important work done in connection with St. Thomas's hospital by Miss Nightingale, which had had such a wide influence on nursing throughout the country, and he then briefly traced the history of the hospital from its foundation in 1551 to the present day. It was said by some people that they would not support the hospital because in incurring their enormous expenses they had followed the fads of the medical men. That was not so, and he did not believe that the general public held such an opinion. Since 1871 the population around the hospital had increased from 644 000 to 961 000 in 1891, and at the present time it was upwards of 1,000,000. The number of patients admitted to the wards in 1894 was 5840, and they stayed on an average 22 7 days under treatment. There were also 24,082 out-patients and 82 782 casualty patients who received attention. Out of the Samaritan Fund 670 persons were given assistance at a cost of £1159 12s. 9d., 400 cases being sent to convalescent homes and the remaining 270 being aided in various ways, such as being supplied with surgical appliances, grants of money to redeem tools and clothing from pawn, and for travelling. He confidently looked to the public to support an institution that was capable of such vast work—an institution which was really one of the most deserving in the country.

The Bishop of SOUTHWARK, who seconded the resolution, said he believed it fundamentally better to have a few great centres of hospital work than a number of smaller ones.

Sir WILLIAM MACCORMAC testified to the important work done by the hospital, remarking that it would be nothing short of a national scandal if the hospital were allowed to remain in its present state.

The Rev. Dr. NEWMAN HALL supported the motion, which was carried unanimously.

On the motion of the Earl of LEVEN and MELVILLE, in the absence of Sir Albert Rollit, M.P., the following motion was supported by Dr. J. F. PAYNE and the Rev. DAVID MACEWAN, and carried: "That taking into consideration the

noble work accomplished by the hospital since its foundation in 1551, both as a medical charity and also as one of the leading schools of medicine and surgery in the kingdom, this meeting views with considerable alarm the falling off of its income from country estates, and records its opinion that an effort should be made to obtain the sum of £100,000, with the view of enabling the at present closed wards to be opened for the free treatment of the poor of this great metropolis."

Alderman Sir STUART KNILL proposed the following resolution: "That, bearing in mind that originally the hospital was placed by King Edward VI. under the fostering care of the mayor, commonalty and citizens of London, the great City Guilds and the citizens of London generally be specially invited to consider the importance of supporting this appeal."

Sir HENRY DOULTON seconded and Mr. F. A. BEVAN supported the resolution, which was carried.

Before proposing a vote of thanks to the Lord Mayor for the great interest he had shown in the prosperity of St. Thomas's Hospital, Mr. J. G. Wainwright (treasurer of the hospital) gave some statistics showing the loss the hospital had sustained through the great agricultural depression. A farm from which the hospital a few years ago was receiving £1270 per annum, and upon which £2000 had been expended, was three weeks ago let for £385. Another farm had depreciated from £1320 per annum to £600 and others from £637 to £221, from £250 to £100, from £406 to £200, from £381 to £100, from £280 to £200, from £600 to £330, and from £780 to £449. The hospital was rated by the parish at £2450. Although they paid the parish these enormous rates over 2000 maternity cases were attended to for the parish. There was not the slightest ground for the rumour which had been started with reference to the unsanitary condition of the buildings, and Mr. Wainwright read a letter from the surveyor to this effect.

Mr. A. O. MACKELLAR seconded the vote of thanks to the Lord Mayor, and the usual courtesies to the chair brought the meeting to a close.

The receipt of the following donations towards the £100,000 asked for were announced during the course of the meeting: Her Majesty the Queen, £100; Duke of Devonshire, 100 guineas; Miss Florence Nightingale, £100; and Mr. Deputy Creasy, 10 guineas. A working man—a former patient—sent a donation of 5s.

THE LONDON COUNTY COUNCIL AND CORONERS' INQUESTS.

At the weekly meeting of the London County Council, held on Tuesday afternoon, the adjourned report of the Public Control Committee on the subject of coroners' inquests was discussed at some length. The following recommendations, the first six of which are, *ipsisima verba*, the suggestions of Sir Walter Foster's Select Committee upon Death Certification, were submitted:—

- (a) That in no case should a death be registered without production of a certificate of the cause of death, signed by a registered medical practitioner or by a coroner after inquest.
- (b) That a medical practitioner in attendance should be required, before giving a certificate of death, to personally inspect the body and identify it as the body of the person he has attended, and should include in his certificate a statement pointing to the absence of accident, poison, violence, or criminal neglect.
- (c) That a form of certificate of death should be prescribed, and that in giving a certificate medical practitioners should be required to use such form.
- (d) That medical practitioners should be required to send certificates of death to the registrar instead of handing them to the representatives of the deceased.
- (e) That it should be made a penal offence to bury or otherwise dispose of a body without an order from the registrar stating the place and mode of disposal, which order, after it has been acted upon, should be returned to the registrar who issued it.
- (f) That it should be made an offence to retain a dead body unburied or otherwise legally disposed of beyond a period not exceeding eight days, except by permission of a magistrate.
- (g) That the certificate should be endorsed by the burial authority, with the date of interment or disposal and the place where the body is buried, and returned to the registrar by the burial authority.
- (h) That when the medical practitioner is unable to certify he should be required to report direct to the coroner. Relatives, friends, and others having cognisance of suspected cases should also be required to report them to the coroner.
- (i) That every case of death after surgical operation should be reported to the coroner with a view to preliminary inquiry, and if necessary the holding of an inquest.

(j) That medical investigators should be appointed: (1) To inquire into causes of all uncertified deaths, assisted by qualified and responsible inquiry officers. (2) To examine the body in all such cases, and make post-mortem examinations where necessary. (3) To report the results to the coroners sitting in court, who will then decide as to the necessity for holding formal inquests. (4) To give evidence at inquests and act as medical advisers to the coroners.

(k) That London should be divided into districts so arranged as to give approximately equal amount of work, and that coroners be paid by salary, not dependent on the number of inquests held.

(l) That franchise districts should be abolished.

(m) That a court or courts should be provided for each district, with a coroner, clerk, inquiry officers, and other necessary officials as in police courts.

(n) That one or more medical investigators should be attached to each court and be paid by salary.

(o) That the office of deputy coroner should be abolished as unnecessary in London.

(p) That inquests should be held and evidence taken by the coroners in all cases where the reports of the medical investigators show further inquiry to be necessary, and in all cases of violent or suspicious death.

(q) That viewing the body, except by the medical investigator and for purposes of identification, should no longer be obligatory.

(r) That the number of jurymen should be reduced to one-half of the present number—i.e., to not less than six or more than eleven.

(s) That in cases involving subsequent criminal proceedings, such as murder or manslaughter, or other criminal offence, the coroner should have full power to commit, and to bind over all witnesses; and further investigation by magistrates in such cases should not be required.

(t) That proper records of all cases dealt with by the court, whether inquests be held or not, should be kept as records of the county.

(u) That the court should have jurisdiction in cases where the body is lying in the district to which it is attached, except in cases of accident &c. where more than one death has taken place, when the jurisdiction shall be with the court for the district in which such accident &c. occurred.

(v) That the committee be authorised to attend as a deputation before the Lord Chancellor in support of the amendment of the law relating to coroners' inquests in the county of London in accordance with these recommendations.

All these clauses were adopted as submitted, save that to clause (b) words were added to the effect that "coroners should be required to accept evidence from representatives of the families of the deceased where it is alleged that death has been caused by accident"; and that to clause (v) words were added to the effect that "the Public Control Committee be instructed to urge the advisability of paying jurymen a sum sufficient to compensate a workman for the actual loss of time incurred in performing the duty, and of making it compulsory that coroners' juries should be summoned by rota." With the majority of these points we have dealt at different times, so that our readers are familiar with our views; but we shall return to the subject next week.

Public Health and Poor Law.

SCOTCH URBAN MORTALITY IN 1894.

LOWEST DEATH-RATE ON RECORD.

ABOUT 36 per cent. of the population of Scotland reside in the eight principal towns, which are estimated to have contained 1,482,962 inhabitants as at the middle of 1894, the computed enumeration of all Scotland at the same date being 4,124,691. We have gone through the laborious process of piecing together the items in the Scotch Registrar-General's monthly returns applicable to these eight cities, and we now present the results for the whole of last year. The combined registration area of these eight chief towns is 40,340 acres, giving an average of 36 330 persons to an acre. In round numbers there are only 14 persons to the acre in Perth, 19 in Aberdeen, and 20 in Paisley; while in Leith the density of the population rises to 35 per acre, Dundee coming next with 38, Greenock with 43 Edinburgh with 44, and Glasgow with 60. The estimated population of Glasgow is 686,820; of Edinburgh, 270,588; Dundee, 158,719; Aberdeen, 131,642; Leith, 72,003; Paisley, 70,363; Greenock, 62,400; and Perth, 30,232. With regard to climatic conditions, on striking a balance for a whole year the average state of matters may be considered as practically the same for the whole of the eight towns.

In these eight towns together there occurred last year from all causes 28,110 deaths. Of these, 14,145 were those of males and 13,965 those of females. The general mortality was thus, notwithstanding the increase of population, below that for 1893, which amounted to 31,606 (males, 15,979; females, 15,627).

females, 15,827). Not only was it absolutely lower, but when the increase of population is taken into account the diminution becomes more conspicuous. Last year the total deaths in the eight towns combined were at the rate of only 191 per 10,000 of their estimated gross population, while in the year previous the rate was 217. For lowness of death-rate last year breaks the record, which extends back for forty years—viz., to 1855, the first year under the Registration Acts for Scotland. The year 1888, with 193 deaths per 10,000 inhabitants, is next lowest. The worst year on record of the whole forty was 1864, with 307 deaths per 10,000 of population. In each of the months of last year the deaths, allowing for greater population, were below the average for the corresponding month during the last ten years. The 28,110 deaths were divided among the different months as follows: January, 2846; February, 2310; March, 2524; April, 2405; May, 2409; June, 2165; July, 2021; August, 1939; September, 1784; October, 2335; November, 2592; December, 2780. Keeping in view that February was three days shorter than October, it will be seen that the mortality was heaviest in the cold months—viz., January to March inclusive, November and December. The first quarter of the year shows 1936 deaths more than the third quarter. The fall in the number of deaths in the third quarter, as compared with the first, applies to all the age divisions, the infant class (under five) benefiting by 896, the adolescent (five to twenty) by 58, the adult (twenty to sixty) by 538, and the aged (sixty and upwards) by 444. Summer was therefore most salubrious for all ages. January, "the coldest month in all the year," is usually the most fatal, being especially severe on the aged and on very young infants. Last year proved no exception. Of the 28,110 deaths, 10,448 were those of children under five years of age (including 6168 infants under one year old), 2519 those of adolescents, 9212 those of adults, and 5931 those of aged persons. The infantile mortality (0-5) was higher in December than in any other month of the year, being 43·8 per cent. of the whole deaths for that month. Over the whole year it constituted 37·17 per cent. of the gross mortality of the eight towns. The most disastrous month for the aged was January, which witnessed the departure of 650 persons 60 years of age and upwards. September and August had the lowest record in this class—viz., 416 and 417 respectively. No centenarians died during the year; but 85 persons between 90 and 100 years of age joined the majority. Females as usual show most vitality, 63 of these 85 nonagenarians being women, while only 17 were men. Two widows are said to have each been 99 years of age at death.

The 28,110 deaths were distributed as follows, the towns being given in the order of their population: Glasgow, 13,674; Edinburgh, 4745; Dundee, 2992; Aberdeen, 2454; Leith, 1213; Paisley, 1258; Greenock, 1200; Perth, 574. The estimated population of each of the eight towns is given above. Making the necessary calculations, we find that the death-rate for last year per 1000 of estimated population was, in Leith, 16·84; Edinburgh, 17·53; Paisley, 17·87; Aberdeen, 18·64; Dundee, 18·85; Perth, 18·86; Greenock, 19·23; and Glasgow, 19·90. For the previous year Aberdeen took the most favourable position with 18·47, followed by Leith with 19·10 and Edinburgh with 19·68, Glasgow showing the highest ratio—namely, 23·30. The death-rate for 1894 was lower than that for 1893 in all the eight towns except Aberdeen, which lost its position owing to the heavy mortality there in December last, arising chiefly from an extensive epidemic of measles and the prevalence of bronchitis. Taking the mean of the ten years 1883-92, Edinburgh, Leith, and Perth, with 1·97 deaths per cent. of population, were the healthiest towns, Aberdeen coming next with 2·00, followed by Dundee with 2·13, Greenock 2·21, Paisley 2·34, and Glasgow with 2·43. In every hundred of the total deaths in Edinburgh and Perth last year about 31 were those of children under five years of age, the rate in Paisley and Leith being 36 fully, in Greenock nearly 38, in Glasgow almost 39, in Aberdeen a little above 39, and in Dundee somewhat under 40. These rates are all lower than in the previous year, except as regards Aberdeen, which shows a rise of 7 per cent., due in great measure to the measles epidemic referred to.

Of the 28,110 deaths 3853 arose from specific febrile or zymotic diseases, 6 from parasitic diseases, 114 from dietetic diseases, 5616 from constitutional diseases, 1890 from developmental diseases, 14,388 from local diseases, 1051 from violence, and 1192 from insufficiently specified causes. To refer more particularly to diseases, there were 2918 of the deaths from miasmatic diseases, 518 from diarrhoeal, 10 from

malarial, 1 from zoonogenous, 124 from venereal, and 32 from septic diseases; 3201 from diseases of the nervous system, 59 from diseases of organs of special sense, 2479 from diseases of the circulatory system, 5434 of the respiratory system, 1917 of the digestive system, 28 of the lymphatic system and ductless glands, 777 of the urinary system, 105 of the organs of generation, and the same number from diseases of parturition, being together 210 from diseases of the reproductive system, 189 from diseases of the organs of locomotion, and 94 from diseases of the integumentary system. Last year owes its low death-rate to a great extent to the small number of deaths from zymotic diseases. As stated, only 2918 deaths arose from miasmatic diseases, showing that there were few serious epidemics. The diarrhoeal deaths occasionally affect the summer mortality materially, but during the whole of last year there were only 9 deaths from simple cholera and 509 from diarrhoea and dysentery together, fatal cases of the two latter being most numerous (88) in August, when also 6 of the deaths from simple cholera happened. Last year there were in the eight towns collectively 113 deaths from small-pox, as against 40 only in 1893. Of these 113, 57 deaths occurred in Edinburgh, 48 in Leith, 5 in Glasgow, and 1 each in Dundee, Aberdeen, and Greenock. Whooping-cough prevailed most extensively from January to May inclusive, carrying off 1110 persons, nearly all children under five years of age, as against 1111 for the previous year. Diphtheria caused 472 deaths, as compared with 424 in 1893. Scarlet fever had 350 deaths ascribed to it last year, as contrasted with 400 in the preceding year, and measles caused only 420 deaths in 1894, compared with 1535 in 1893. There were few deaths last year from this cause until the month of December, when measles became epidemic in Aberdeen and Glasgow. The deaths from influenza fell from 291 in 1893 to 147 last year. Typhoid fever tends to diminish in the towns, but infection is often conveyed into them by milk from country districts. Last year the deaths in the eight towns from enteric fever numbered 255, compared with 279 the year before. Typhus fever, from the exertions to prevent overcrowding, has become almost unknown. Only 19 deaths were due to that cause in 1894 and 35 in 1893. The mortality from puerperal fever last year was 112. Directly caused by intemperance were 87 deaths last year and 116 in the year previous; of these 87, 73 were ascribed to chronic alcoholism and 14 to delirium tremens. Pulmonary phthisis, or consumption, was the deadliest disease, cutting off 3019, principally young people, there being 2902 from the same evil in the previous year. The relative frequency of phthisis last year is as follows: in Perth the mortality was at the rate of 16·10 per 10,000 inhabitants; Paisley, 16·48; Edinburgh, 17·00; Aberdeen, 18·00; Leith, 19·30; Greenock, 20·99; Dundee, 21·23; and Glasgow, 22·58. In 1893 the highest mortality from phthisis occurred in Paisley, Edinburgh, Aberdeen, Leith, and Perth. Among the other constitutional diseases cancer is the most fatal. Last year there were 1119 deaths from that cause, being a rise of 82 on the previous year. In 1893 cancer was most marked in Edinburgh, Aberdeen, and Leith. Last year's figures show great divergences as to the relative prevalence of the disease in the various towns. In Perth the mortality from cancer was only 4·60 per 10,000 inhabitants, and in Paisley it was 4·97; but in Greenock it was 5·93; in Leith, 6·25; Glasgow, 6·77; Dundee, 7·43; Aberdeen, 8·29; and in Edinburgh 10·94. The high ratio in Aberdeen and Edinburgh, especially the latter, is noticeable, keeping in view the 1893 result. From affections of the respiratory organs (not including pulmonary phthisis and whooping-cough, which have been already mentioned as included in other classes) there were 5434 deaths last year. This figure includes 2457 deaths from bronchitis, which in the year before claimed 2978 victims, and was the most fatal individual disease for that period. In Aberdeen last year bronchitis cut off 19·52 per 10,000 inhabitants, the ratio in Dundee being 18·84, in Glasgow 16·80 in Edinburgh 14·59, and in Leith 12·36. There succumbed to pneumonia last year in the eight towns collectively 2158 persons, as compared with 2640 in 1893. In Edinburgh last year the deaths from pneumonia were at the rate of 11·53 per 10,000 of population, in Aberdeen 11·69, in Leith 11·94, in Dundee 16·38, and in Glasgow 16·44; while in the previous year Edinburgh, Glasgow, and Dundee had the highest ratios. Croup is responsible for 297 deaths in 1894. Heart diseases are accountable for 2479 deaths last year, the mortality from diseases of the circulatory system in 1893 having been 2347. January gave the most fatal monthly record in 1894

under this head. The 2479 deaths include 2065 from endocarditis, the monthly mortality from which varied from 203 in January to 128 in September, August being the next lowest with 139. Last year the deaths from valvular disease of the heart were at the rate of 8.50 per 10,000 of population in Aberdeen, 13.29 in Dundee, 13.30 in Greenock, 13.35 in Glasgow, 14.99 in Leith, 15.34 in Edinburgh, 15.35 in Paisley, and 16.43 in Perth.

In Glasgow last year there were registered the deaths of 2940 children under one year of age, 906 in Edinburgh, 759 in Dundee, 621 in Aberdeen, 294 in Leith, 273 in Paisley, 268 in Greenock, and 107 in Perth. The cause of death in 803 of these 6168 cases was certified as being premature birth debility. Thirty children under five were suffocated in bed, and 15 suffocated otherwise during the year. Last year there were 963 deaths due to apoplexy, and the cause of 578 others is given as "hemiplegia, brain paralysis." "Old age" simply is put down as the cause of 916 deaths, January giving the largest contribution (100) of any of the months, and August (54) and July (59) the lowest; 981 deaths were due to accidents or negligence, being rather more than in the previous year, when these numbered 969. Six persons lost their lives by "homicide." There were no executions, but 64 persons committed suicide last year. "Debility, atrophy, inanition" is given as the cause of 929 deaths, of which 460 were those of children under five years of age. There occurred last year 136 deaths from causes not specified.

The urban mortality for 1893 was low, principally owing to there being few epidemics. That for 1894 is lower still, partly owing to a similar absence of zymotic diseases, including influenza. Further, the heat in the summer months was not great, and there were frequent rainfalls. As to the winter, although January was stormy and colder than usual, there was an absence of "hard" weather in February, and the mean temperature in March was above previous averages. Generally speaking the decrease in the death-rate is evidence of the earnest work carried out by sanitary officers and authorities to promote the public health.

ENTERIC FEVER MORTALITY IN 1893.

THE recrudescence of enteric fever mortality in 1893 was one of the most notable features in the statistics for that year dealt with in the Registrar-General's annual report recently issued. The annual death-rate from this disease in England and Wales, which was equal to 326 per million in the ten years 1871-80, declined to 193 in the succeeding ten years 1881-90, the largest decline occurring in the latter part of that decade. The rate was 236 per million in 1884, but was below 200 in each of the six years 1885-90. In 1891 and 1892 the rate further fell to 168 and 137; whereas in 1893, probably under the influence of the long drought and high temperature, the enteric fever death-rate rose again to 229, a higher rate than in any preceding year since 1884, when it was 236 per million. The rate from this disease in the various English counties showed remarkably wide variations. The lowest rates per million were 58 in Wiltshire and Oxfordshire, 66 in Buckinghamshire, and 73 in Berkshire. Even in the vast urban population of London the rate did not exceed 160 per million and was 69 below the mean rate in the whole of England and Wales. The highest rates were 320 in Lancashire, 326 in the North Riding of Yorkshire, 448 in Sussex (due to the disastrous epidemic in Worthing), 487 in the East Riding of Yorkshire, and 565 in Durham. In seven other counties and in South Wales the rate exceeded the mean rate in England and Wales. The remarkable fatality of this disease in a group of registration districts situated for the most part in Durham, but also extending into Northumberland and into the northern parts of Yorkshire, to which especial attention had been directed in the Registrar-General's reports for 1890, 1891, and 1892, showed a further increase in 1893. The enteric fever death-rate in this group of eighteen registration districts was equal to 395 per million in 1890; it fell to 301 and 181 in 1891 and 1892, but rose to 480 per million in 1893, and was more than double the mean rate in England and Wales in the same year. The excess of the rates in some of these registration districts in 1893 calls for special notice. The rate was 510 in Middlesbrough, 693 in Chester-le-Street, 836 in Sunderland, 977 in Auckland, 1112 in Easington, and 1163 in Houghton-le-Spring. Taking the mean rate in the four years 1890-93, the highest rates were 528 in Auckland, 540 in Stockton, 544 in Houghton-le-Spring, 559 in Easington, and 633 in Middlesbrough. Such rates,

from a preventable disease like enteric fever, during a period of four years, call for the active intervention of the central health authority, since it affords abundant evidence of ineffective and negligent local sanitation. A local epidemic of enteric fever of four years' duration should be recognised in the present day as conclusive condemnation of the sanitary authority charged with the health responsibility for the district. We venture to hope that the terrible figures from the Registrar-General's last annual report to which we have called attention will serve to awaken the sanitary authorities of the county of Durham to the urgent need for vigorous action with a view to check this scourge of enteric fever prevalence which caused so heavy a rate of death and suffering during the four years 1890-93.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Derbyshire County Sanitary District.—The vital statistics of this administrative county, which contained at the last census 426,768 persons, are well set forth by Dr. Sidney Barwise in the accompanying table.

District.	Rates per 1000 of population.			Deaths of children under one year to every 1000 births.
	Births.	Deaths from all causes.	Deaths from seven chief zymotics.	
Rural districts of Derbyshire ...	34.8	16.6	1.8	129
Urban districts of Derbyshire ...	35.7	18.9	2.4	171
Whole administrative county ...	35.3	17.5	2.1	149
England and Wales... ..	30.8	19.2	2.47	159

The statistics in reference to small-pox and vaccination we have already noticed in our columns.¹ There were 105 deaths from measles in the county during 1893, and Dr. Barwise advises that some arrangement should be made by which the school attendance officers should notify to the medical officers of health cases of measles which they come across in the course of their duties. Out of the whole population of the county there are still 55,304 to whom the Notification Act does not at present apply. Dr. Barwise has presented to the county council an exhaustive report on the hospital provision of the county, and he points out that in 1893 only 1 per cent. of the scarlet fever cases were removed to hospital, 3.7 per cent. of typhoid fever cases, and not a single case of diphtheria. The whole county has been mapped out into twelve hospital districts, and Dr. Barwise calculates that by erecting twelve hospitals in suitable positions 421,000 of the population of the county would be within eight miles of a hospital, and all the urban districts and workhouses within six miles. There are at present but two steam disinfectors in the county, and the provision of an apparatus at each proposed hospital would serve the requirements of each hospital district. Much progress in the matter of sewage purification is being made throughout the county, and Dr. Barwise is making systematic examination of the rivers in order to be in a position to compare their subsequent condition with the present. The analyses already made of the Derwent are very interesting, the river showing a gradually increasing amount of free and albuminous ammonia as far as Derby, but after this town has been passed the organic matter is more than doubled.

Stapleton Urban Sanitary District.—Small-pox was the disease with which Dr. William Brown had chiefly to deal during 1894, and it seems that the vast majority of the cases occurred in Barton Regis workhouse and Eastville, the district abutting upon the workhouse. Special means of isolation have since been provided by the sanitary authority, and Dr. Brown expresses the hope that for the future there will be no especial incidence of small-pox upon the workhouse and the district adjoining it.

Kingston upon Thames Urban Sanitary District.—Mr. Beale Collins, in his annual report for 1894, devotes considerable space to a consideration of the proposed extension of the borough boundaries, so as to include the ecclesiastical parishes of Kingston and Ham. He discusses the manner in

¹ THE LANCET, Feb. 2nd, 1895.

which such extension would modify the present age, sex, and class distribution of the borough, and thus affect the birth, death, and disease rates. In dealing with the arrangements for isolation accommodation Mr. Collins shows that much advantage both as regards efficiency and economy would be gained by providing one large hospital for the whole district instead of several small ones. In short, Mr. Collins thinks that an amalgamation such as that proposed will be likely to afford the sanitary authority "greater facility in dealing with outbreaks of disease, and to give the best practical working scheme for draining the whole of the district." In the matter of vaccination Mr. Collins suggests, among other things, that all persons having conscientious scruples against vaccination should be compelled to register themselves and their families as unvaccinated, and that only by this means should they be exempt from prosecution for non-vaccination; he also suggests that all persons registering themselves as vaccinated or revaccinated should receive a small fee in return for services rendered to the State. Mr. Collins thinks that some such regulations as these would ensure a thorough vaccination of the community with little or no increase of expenditure, "as the vaccination officers could be almost entirely dispensed with and small-pox hospitals would not be required." We must confess we are not so sanguine as Mr. Collins as to the good effect of the means he proposes, and we think that the possibility of evading vaccination by registration would be widely taken advantage of, so much so indeed that small-pox hospitals would be as much a necessity as at the present time.

Aston Manor Urban Sanitary District.—Mr. Henry May is always prompt in the compilation of his annual reports, and that now before us is one of the earliest we have received for 1894. The general death-rate for the year in question was but 14 per 1000, the lowest on record for the last twenty-one years with the exception of 1885, when the rate was 13.9. The Warwickshire County Council, advertising to Mr. May's report for 1893, wrote to the Aston urban sanitary authority expressing their opinion that no charge should be made for the admission of patients to the fever hospital. The Aston sanitary authority, however, apparently resented this action on the part of the county council, and replied that they were unaware of any case where admission had been refused and that it was their practice to excuse the fee in the case of patients being unable to afford it. Experience has certainly shown that charges for admission to the general wards of a fever hospital are undesirable, but perhaps this is a question which may on the whole be left to the discretion of local authorities.

Kettering Urban Sanitary District.—The general death-rate of this district during 1894 was 14.9 per 1000 and the zymotic death-rate 2.4 per 1000. Phthisis has, Mr. Winter Dryland reports, claimed fewer victims in Kettering in proportion as new factories with improved methods of ventilation and more air space have sprung up; but it seems that in a large number of cases pneumonia and bronchitis have occurred in newly erected houses occupied before the walls were perfectly dry. In referring to infantile mortality Mr. Dryland points out that, if the mothers of Kettering would be guided by their medical attendants as to the feeding of their infants, many lives might be spared. Many of the cases of scarlet fever which occurred during 1894 were, Mr. Dryland states, followed by rheumatism, and he attributes this to want of care during slight attacks. There seems to be a good prospect of a joint fever hospital being shortly procured by the Kettering urban and rural district councils.

Mirfield Urban Sanitary District.—In his annual report for 1893 Mr. Thomas Fairclough states that the water-supply of the district has been abundant notwithstanding the exceptionally dry spring and summer. He reports, however, that it is still necessary to draw off the water which has been standing in the lead service pipes and also to filter it through a charcoal filter before drinking, as the water still retains the power of acting upon lead. He advises that the use of lead service pipes should be discontinued. Mr. Fairclough cannot understand why the Huddersfield corporation are "so obstinate in this water question," as it must eventually be faced and dealt with.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6870 births and 4210 deaths were registered during the week ending

Feb. 9th. The annual rate of mortality in these towns, which had been 18.7 and 19.7 per 1000 in the two preceding weeks, further rose last week to 20.7. In London the rate was 21.0 per 1000, while it averaged 20.4 in the thirty-two provincial towns. The lowest rates in these towns were 13.5 in Derby, 14.5 in Leicester, 15.0 in Bradford and in West Ham, and 15.2 in Gateshead; the highest rates were 23.8 in Birkenhead, 24.0 in Plymouth, 24.8 in Manchester, 27.1 in Bolton, and 30.9 in Liverpool. The 4210 deaths included 312 which were referred to the principal zymotic diseases, against 328 and 299 in the two preceding weeks; of these, 78 resulted from whooping-cough, 67 from diphtheria, 56 from measles, 39 from diarrhoea, 36 from "fever" (principally enteric), 32 from scarlet fever, and 4 from small-pox. No fatal case of any of these diseases occurred last week in Swansea; in the other towns they caused the lowest death-rates in Bristol, West Ham, Bradford, Leeds, and Hull, and the highest rates in Croydon, Blackburn, Manchester, Gateshead, and Plymouth. The greatest mortality from measles occurred in Croydon, Plymouth, Bolton, Preston, and Halifax; from whooping-cough in Plymouth, Oldham, Burnley, Blackburn, and Gateshead; and from "fever" in Birkenhead and Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 67 deaths from diphtheria included 34 in London, 5 in Birmingham, 5 in Manchester, 3 in Wolverhampton, and 3 in Liverpool. Three fatal cases of small-pox were registered in London, and 1 in Derby, but not one in any other of the thirty-three towns. There were 56 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 9th inst., against 32, 35, and 51 at the end of the three preceding weeks; 18 new cases were admitted during the week, against 6, 8, and 21 in the three preceding weeks. The number of scarlet-fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1667, against 1653, 1662, and 1653 on the three preceding Saturdays; 149 new cases were admitted during the week, against 154, 186, and 160 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 324 and 377 in the two preceding weeks, further increased last week to 480, and slightly exceeded the corrected average. The causes of 86, or 2.0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Cardiff, Leeds, Sunderland, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 28.3 to 23.9 per 1000, rose again to 26.2 during the week ending Feb. 9th, and exceeded by 5.5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17.5 in Dundee and 20.5 in Edinburgh to 26.0 in Greenock and 32.4 in Glasgow. The 757 deaths in these towns included 27 which were referred to whooping-cough, 26 to measles, 8 to diarrhoea, 7 to diphtheria, 6 to "fever," 4 to scarlet fever, and 3 to small-pox. In all, 81 deaths resulted from these principal zymotic diseases, against 92 and 89 in the two preceding weeks. These 81 deaths were equal to an annual rate of 2.8 per 1000, which was 1.3 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 18 and 25 in the two preceding weeks, further rose to 27 last week, of which 20 occurred in Glasgow. The deaths referred to measles, which had declined from 58 to 37 in the four preceding weeks, further fell to 26 last week, and included 10 in Glasgow, 9 in Aberdeen, and 4 in Edinburgh. The fatal cases of diphtheria, which had been 9, 5, and 3 in the preceding three weeks, rose again to 7 last week, of which 4 occurred in Glasgow. The 6 deaths referred to different forms of "fever" corresponded with the number in the preceding week, and included 3 in Edinburgh and 2 in Glasgow. Of the 3 fatal cases of small-pox, 2 were recorded in Edinburgh and 1 in Glasgow. The deaths referred to diseases of the

respiratory organs in these towns, which had been 186 and 168 in the two preceding weeks, rose again to 214 last week, and exceeded by 93 the number in the corresponding period of last year. The causes of 43, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31.0 and 31.9 per 1000 in the two preceding weeks, was again 31.9 during the week ending Feb. 9th. During the past six weeks of the current quarter the death-rate in the city has averaged 32.5 per 1000, against 19.1 in London and 23.2 in Edinburgh. The 214 deaths registered in Dublin during the week under notice corresponded with the number in the previous week, and included 19 which were referred to the principal zymotic diseases, against numbers declining from 23 to 16 in the three preceding weeks; of these, 7 resulted from small-pox, 5 from whooping-cough, 4 from "fever," 2 from diarrhoea, 1 from scarlet fever, and not one either from measles or diphtheria. These 19 deaths were equal to an annual rate of 2.8 per 1000, the zymotic death-rate during the same period being 1.5 in London and 2.5 in Edinburgh. The fatal cases of small-pox, which had declined from 11 to 5 in the four preceding three weeks, rose again to 7 last week. The 5 deaths from whooping-cough showed a further increase upon the numbers recorded in recent weeks. The deaths referred to different forms of "fever," which had been 5 and 4 in the two preceding weeks, were again 4 last week. The 214 deaths in Dublin last week included 35 of infants under one year of age and 66 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed an increase upon those recorded in the preceding week. Eight inquest cases and 4 deaths from violence were registered; and 75, or one third, of the deaths occurred in public institutions. The causes of 21, or nearly 10 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during January in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7.0 per 1000 of the population, estimated at 4,392,346 persons in the middle of this year. In the three preceding months the rates had been 10.0, 9.5, and 8.4 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, St. Giles, Strand, St. Olave Southwark, Lewisham, and Woolwich; while they showed the largest excess in Marylebone, St. Pancras, Limehouse, Mile End Old Town, Poplar, Rotherhithe, Battersea, and Plumstead. The prevalence of small-pox in London showed an increase during January, 53 cases being notified during the month, including 39 in Marylebone, 5 in Battersea, and 3 in Greenwich sanitary areas. The Metropolitan Asylum Hospitals contained 51 small-pox patients at the end of January, against numbers declining from 93 to 16 at the end of the four preceding months; the weekly admissions averaged 10, against 9, 6, and 3 in the three preceding months. The prevalence of scarlet fever in London showed a slight further decline from that recorded in recent months; this disease was proportionally most prevalent in St. James Westminster, Bethnal Green, Limehouse, Mile End Old Town, Poplar, Rotherhithe, Battersea, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1633 scarlet fever patients at the end of January, against 2207, 2114, and 1865 at the end of the three preceding months; the weekly admissions averaged 148, against 246, 208, and 171 in the three preceding months. The prevalence of diphtheria in London showed a marked further decline during January; among the various sanitary areas this disease showed the highest proportional prevalence in St. Luke, Whitechapel, St. George-in-the-East, Mile End Old Town, Poplar, St. Saviour Southwark, Rotherhithe, and Battersea. There were 515 cases of diphtheria under treatment in the Metropolitan Asylum hospitals at the end of January, against 537, 517, and 521 at the end of the three

preceding months; the weekly admissions averaged 71, against 100, 90, and 93 in the three preceding months. The prevalence of enteric fever in London also showed a marked decline during the month under notice; among the various sanitary areas this disease showed the highest proportional prevalence in St. Martin-in-the-Fields, Strand, St. George Southwark, Rotherhithe, and Lee sanitary areas. Erysipelas was proportionally most prevalent in Marylebone, St. Pancras, Bethnal Green, Whitechapel, Mile End Old Town, and Poplar sanitary areas. The prevalence of puerperal fever showed a marked increase during January, and considerably exceeded that recorded in any recent month; the 41 cases notified during the five weeks ending Feb. 2nd included 9 in St. Pancras, 6 in Camberwell, 4 in Lambeth, 4 in Hackney, 3 in Islington, and 3 in Chelsea sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, Feb. 2nd, the deaths of 7691 persons belonging to London were registered, equal to an annual rate of 18.3 per 1000, against 15.8, 15.2, and 17.7 in the three preceding months. The lowest death-rates during January in the various sanitary areas were 6.2 in Lee, 10.8 in Hampstead, 11.5 in Stoke Newington, 14.4 in St. George Hanover-square, 14.7 in Wandsworth, and 15.1 in Westminster and in Lewisham; the highest rates were 24.7 in St. Saviour Southwark, 25.5 in St. Giles, 25.6 in Holborn, 26.1 in St. George-in-the-East, 26.6 in Limehouse, 27.6 in St. Luke, and 29.6 in Strand. During the five weeks of January 656 deaths were referred to the principal zymotic diseases in London; of these, 3 resulted from small-pox, 133 from measles, 53 from scarlet fever, 187 from diphtheria, 136 from whooping-cough, 76 from enteric fever, 1 from an ill-defined form of "fever," and 67 from diarrhoea. These 656 deaths were equal to an annual rate of 1.6 per 1000, against 1.6 and 1.8 in the two preceding months. No fatal case of any of these diseases was recorded last month in St. James Westminster; in the other sanitary areas they caused the lowest death-rates in St. James Westminster, Marylebone, Hampstead, St. Saviour Southwark, and Bermondsey; and the highest rates in Chelsea, Strand, Holborn, St. George-in-the-East, Limehouse, Poplar, Lee, and Plumstead. Only 3 fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 22; these 3 cases belonged to Marylebone sanitary area. The 133 deaths referred to measles were little more than half the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Paddington, Holborn, Bethnal Green, Poplar, Greenwich, and Plumstead. The 53 fatal cases of scarlet fever were only half the corrected average number; this disease was proportionately most fatal in Poplar sanitary area. The 187 deaths from diphtheria exceeded by 35 the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Bethnal Green, St. George-in-the-East, Mile End Old Town, Poplar, Newington, and Plumstead. The 136 fatal cases of whooping-cough were less than a third of the corrected average number; among the various sanitary areas this disease was proportionately most fatal in Clerkenwell, Shoreditch, St. George-in-the-East, Limehouse, Battersea, and Lee. The 76 deaths referred to enteric fever slightly exceeded the corrected average number; this disease showed the highest proportional fatality in Strand and City of London sanitary areas. The 67 fatal cases of diarrhoea were within 3 of the corrected average number. In conclusion, it may be stated that the mortality in London during the month under notice from these principal zymotic diseases was nearly 40 per cent. below the average.

Infant mortality in London during January, measured by the proportion of deaths under one year of age to registered births, was equal to 123 per 1000, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, Strand, St. Olave Southwark, Lewisham, and Plumstead; and the highest rates in St. Martin-in-the-Fields, City of London, St. George-in-the-East, St. Saviour Southwark, Woolwich, and Lee.

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON—JANUARY, 1895.
(Specially compiled for THE LANCET.)

Sanitary area.	Estimated population in the middle of 1896.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.		
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Krysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.†	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhoea.				Total.	Annual rate per 1000 persons living.

† Including deaths from membranous group.

• Including 41 cases of membranous group.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR F. J. JENCKEN, M.B., A.M.S., arrived at Netley for duty on the 1st inst., and is taken on the strength accordingly. Surgeon-Captain R. H. Moore, M.D., who reported his arrival at Netley on the 8th inst., has been granted leave from the 12th inst. to the 12th prox.

ARMY MEDICAL STAFF.

Surgeon-Captain James H. Daly is placed on temporary half-pay on account of ill-health. The under-mentioned Surgeon-Lieutenants to be Surgeon-Captains:—Edgar M. Pilcher, M.B.; Henry P. Johnson; William G. Bests; Harold A. Stalkart, M.B.; Henry N. Dunn, M.B.; Samuel H. Withers, M.B.; Edward M. Morphew; Ernest C. Anderson; Nicholas Tyacke; Robert H. E. Holt; Lionel A. Mitchell, M.B.; Charles C. Fleming, M.B.; John Hennessey, M.B.; Claude B. Martin, M.B.; George J. Buchanan, M.B.; Charles B. Lawson, M.B.; George E. Hughes; Joseph F. M. Kelly, M.B.; Gilbert S. Crawford; and John D. Alexander, M.B.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Colonel D. O'Connell Raye (Bengal), Officiating Inspector-General of Civil Hospitals, Punjab, are replaced at the disposal of the Military Department. The following officers are transferred:—Surgeon-Lieutenant-Colonel J. McConaghy, Civil Surgeon, from Allahabad to Lucknow; Surgeon-Lieutenant-Colonel A. J. Willcocks, Civil Surgeon, to the Agra district; Surgeon-Major C. P. Lukis, Civil Surgeon, from Agra to Shahjahanpur; Surgeon-Captain J. Morwood, Civil Surgeon, from Shahjahanpur to Basti; and Surgeon-Major F. C. Chatterjee, from Basti to Pilibhit; Brigade-Surgeon-Lieutenant-Colonel W. R. Hooper, Civil Surgeon, Lucknow, has retired from the service.

NAVAL MEDICAL SERVICES.

Staff-Surgeon H. S. R. Sparrow is appointed to the Plymouth Division of Marines.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant W. Vernon to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 2nd Cinque Ports (Eastern Division Royal Artillery): Surgeon-Captain F. Shaw resigns his commission. 4th Lancashire: John Cecil Mackmurdo Given, M.D., to be Surgeon-Lieutenant. 5th Lancashire: Douglas John Mayhew Bone, M.B., to be Surgeon-Lieutenant. *Engineers*: 1st Flintshire (Buckley): George Osborne Morgan Lunt, M.B., to be Surgeon-Lieutenant. *Volunteer Infantry Brigade*: Northern Counties Brigade: Surgeon-Lieutenant-Colonel F. B. Mallett, M.D., 2nd Volunteer Battalion the Loyal North Lancashire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel.

"ENTERIC FEVER AT ALDERSHOT."

A correspondent, in a contribution under the above heading to the *Standard* of the 12th inst., calls attention to the various rumours that have been current of late respecting the unhealthiness of Aldershot Camp and the alleged unsatisfactory condition of some of the occupied barracks and quarters and the drainage of the camp, with a view to a question being put to the Secretary of State for War in the House of Commons, so as to elicit information as to the actual state of affairs there. We have from time to time referred to the subject in connexion with the bad and insanitary condition of the sewage farm and other matters, and we alluded last week to the alleged contamination of some of the water supplied to the troops. As regards the latter the correspondent of the *Standard* states that a sample of water taken from the tank supplying the officers' mess of the Tournay Barracks in the Marlborough Lines has been found to be contaminated with animal and vegetable products, and that H.R.H. the Duke of Connaught is reported to have recently forwarded a sample of this water by special messenger to Netley for examination. That the sewage farm for the camp is regarded as a bad one and quite inadequate for the purpose is undoubted, for the Treasury would not otherwise have made a grant of money for providing another in connexion with the Aldershot civil authorities, as has been recently announced; but irrespectively of this there have been so many allegations in different public journals with regard to the barracks themselves, the state of the drainage, and the prevalence of

disease in the camp attributable to preventable causes that it is surely time for the War Minister to enlighten the public as to the truth or otherwise of these rumours.

ABDOMINAL SURGERY ON THE BATTLEFIELD.

We may call the attention of members of the military and naval medical services to the observations of Professor N. Senn, President of the Association of Military Surgeons of the United States and Surgeon-General of the National Guards of Illinois, in regard to this subject, reprinted as a pamphlet from the *St. Louis Clinique* for June, 1894. Professor Senn is firmly convinced that abdominal surgery has a great future before it in military practice, and considers it to be the duty of the military authorities to make ample provision for initiating some well-matured plan of procedure calculated to save life occasionally on the battlefield in cases heretofore beyond the reach of surgery. We are afraid that the conditions of war, the provision of transport, stores, and surgical material, with a *personnel* specially trained to the work, will render abdominal operative surgery extremely difficult of successful accomplishment under such circumstances. Be this as it may, the remarks which Professor Senn makes on penetrating gunshot wounds of the abdomen in regard to the arrest of hæmorrhage and direct treatment of visceral wounds, preparation for laparotomy and operation in the field, together with the practical suggestions he has to offer in order to give effect to his proposals, are very suggestive and well worth reading. The pamphlet is well illustrated.

DISTINGUISHED SERVICE REWARD.

We congratulate Sir Anthony D. Home, V.C., K.C.B., upon having a reward for distinguished service conferred upon him. There can be no doubt about the long and distinguished field services of this officer whilst on the active list of the Army Medical Department, for he took part in the Crimean campaign of 1854-5, in the Indian Mutiny, including the siege and relief of Lucknow, in the China War, the New Zealand War of 1863-65, and in the Ashanti War. It is not easy to beat such a war record as this. Sir Anthony Home, in addition to having earned a V.C. for an exhibition of great personal gallantry during the Indian Mutiny, occupied several very important posts whilst serving in the Medical Department, and was at one time Surgeon-General of Her Majesty's Forces and Principal Medical Officer of India. He also temporarily served on the Medical Department of the Privy Council, and has the reputation of being a man of culture and ability, with an exceptional talent for organisation.

MEDICAL SERVICES IN WAR.

Medical officers of the army may be glad to have their attention directed to a very useful little publication entitled "Notes on Medical Services in War," by Brigade-Surgeon-Lieutenant-Colonel W. H. McNamara (Messrs. Gale and Polden's military series). It sets forth shortly and intelligibly much information which it is necessary for medical officers to know about the requirements of modern war and the peace training necessary to meet them. They cannot readily find this out for themselves, it being nowhere laid down in a succinct and easily accessible form. The author of these "Notes" seems to us to have provided an excellent guide—especially for junior medical officers—at the trifling cost, it may be added, of one shilling.

BACTERIA AND CHIMNEY SMOKE.

Amid the vagaries of the scientific imagination in regard to the methods of diffusion of bacteria and micro-organisms of disease generally the most ingenious and droll seems to be that entertained by the municipal authorities of Bombay who, according to the *Pioneer Mail*, have applied for the services of Mr. E. H. Hankin, the chemical examiner, Government analyst, and bacteriologist for the North-West Provinces and Oudh, to institute an inquiry into the possible influence of chimney smoke in the dissemination of bacteria!

THE POST OF PRINCIPAL MEDICAL OFFICER OF INDIA.

It is currently reported, but it has never been officially announced, so far as we know, that Surgeon-Colonel Gore is to succeed to the appointment of Surgeon-General of Her Majesty's Forces and Principal Medical Officer of India on that post being vacated by the retirement of Surgeon-Major-General Bradshaw, C.B.

Surgeon-Major-General J. Warren, Principal Medical Officer, Bombay Army, will shortly proceed to make his annual inspection of the barracks and hospitals at Aden.

Correspondence.

"Audi alteram partem."

SCHOOL BOARDS AND MEDICAL CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—The question of signing School Board certificates is arriving at a stage in which some concerted action one way or the other appears desirable on the part of the profession; and as the subject is coming up for discussion at our next Hospital Committee I and my colleagues ask for your advice in order that we may adopt a course which shall commend itself to our professional brethren. The School Board for this district in the case of non-attendance at school issue certificates to the parents of the absentee (requiring them to be returned duly filled up and signed by a medical man) of which the following is a copy:—

SCHOOL BOARD FOR WEST HAM.
FORM OF MEDICAL CERTIFICATE.

..... is suffering from 189
and is not now fit to attend school, but will probably be able to return in weeks. The child has been under my care since the 189
(Signed)

* If the child is now fit to attend school have the kindness to strike out the word "not" and the words following "school."
NOTE.—The Board will not be liable for any expense attending the filling up of this certificate.

Doubtless many of these certificates have been filled in and signed gratuitously by medical men as the simplest way of ridding their patients of the irksome visits of the School Board attendance officer, but in the out-patients' room of our hospital we have always declined to sign them, feeling sure that the hospital card which is kept by the patient should be sufficient evidence of illness. Lately, however, a member of the Hospital Committee wrote to the secretary "asking to be informed by whose authority the medical staff refused to sign the above certificate." The matter has been referred to the Staff Committee for report. It has always been our boast that the disease from which our patient is suffering is a private matter between our patient and ourselves. This rule has been broken through by the legislature in the case of the Infectious Diseases (Notification) Act, 1889 in the interests of public health, where the principle is recognised that the medical profession are entitled to a fee from the local sanitary authority for the information supplied. The educational Acts merely cite illness as a legitimate reason for non-attendance at school. Does this imply that the School Board are entitled to know the particular disease which causes the disability? If it does not, then surely the medical man, in filling in the certificate, is committing a breach of professional etiquette. If it does, then the local authority for educational purposes is requiring information in the interest of public education, and should be prepared to pay for it in the same way as the local authority for public health purposes; but quite apart from information our board goes a step further and desires a distinct professional opinion, a professional opinion requiring the greatest development of medical skill—namely, the probable duration of the disease—at the same time intimating to all and sundry its desire to have this professional advice without paying for it. Granting for one moment that the information is desirable, the system of entry of our out-patient department would enable any case of illness to be easily traced throughout the whole course of its attendance, and the information required by the certificate could be supplied to any officer of the School Board appointed to attend the hospital with that object. The cases of bogus illness which the certificates are apparently intended to check must be comparatively few, while the certificates themselves are freely distributed to scholars who do not attend, from which it would appear that the time and skill of the medical profession are to be used in order to save trouble to the school attendance officer, and in order that the School Attendance Committee of the West Ham School Board may render itself efficient by means of the labour of other people. We all here recognise the ability with which the School Board studies the interests of education in this district, and no class is more interested in and desirous of the spread of education than that of medical men, but surely on principle it is time for us to pause when an

important executive department of the country asks us to give it gratuitous advice, and it is proposed that a hospital committee shall recognise the appreciation of the suggestion that it is our duty so to do.

I am, Sirs, yours faithfully,

CHARLES SANDERS.

Romford-road, Stratford, E., Feb. 5th, 1895.

* * We see no reason that the School Board should be informed of the exact medical diagnosis. The fact that under certain circumstances this diagnosis is communicated to the local sanitary authority is sufficient for the safeguarding of public health. We entirely agree with our correspondent that medical services should not be expected by individual or corporation to be given gratuitously, and hope that the hospital committee in question will see the propriety of supporting their medical staff in so reasonable a contention.—ED. L.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."

To the Editors of THE LANCET.

SIRS,—I hold it to be the duty of anyone engaged in a scientific discussion to publicly admit any error of statement which he may have made so soon as his attention has been directed to it. On reading Dr. Pavy's letter and referring again to his book I find that, although his position might have been more clearly stated, I was wrong in supposing that he applied the fermentation test directly to normal urine and not to a product extracted from the urine by a series of chemical processes. I now admit my mistake and express my regret for having made it. Dr. Pavy's comment on my quotation of Sir William Roberts as to the limitation of the fermentation test is unfair and misleading. I have already admitted my error in supposing that Dr. Pavy applied the test to the entire urine and not to an extract therefrom; but while believing the former to have been the method employed it was quite pertinent to indicate that the largest amount of sugar supposed to be present in normal urine could not be shown by the fermentation test. With this simple explanation I leave to the impartial judgment of others whether it is not Dr. Pavy who "has considered himself at liberty to neglect to give consideration to the misleading effects of putting an incomplete representation before your readers."

Again, in suggesting that Dr. Pavy by neutralising his acid fluid by carbonate of soda before he applied the fermentation test was introducing a possible source of error, he facetiously says that I am "indulging in some kind of jest, and that the suggestion borders too much on the absurd to be otherwise than a jest." Dr. Halliburton, however, appears to have thought the suggestion sufficiently reasonable to induce him to perform some experiments, the results of which he recorded in THE LANCET of last week. He found that the acidity of urine to which 1 per cent. of sugar had been added did not prevent fermentation, and that normal acid urine and the same urine neutralised by ammonia did not ferment with yeast, but normal urine neutralised by sodium carbonate with the addition of yeast gave off an abundance of carbonic acid gas. Another tube contained a weak solution of sodium carbonate and yeast, but no urine. Here also gas was given off. One result of my "jest" and of Professor Halliburton's experiments will be that in future Dr. Pavy will not neutralise an acid fluid with sodium carbonate before applying the fermentation test. Since, however, he states that the production of alcohol was ascertained this appears conclusive. It is to be regretted that a scientific discussion cannot be conducted without an unseemly display of personal feeling, and even the suggestion of an "offence to literary probity," to which I do not feel called upon to reply. What would be thought of the doubtful taste displayed if, in referring to Dr. Pavy's persistently ignoring the reducing action of kreatinine, I were to speak of it as "too much bordering on the absurd to be anything but a jest"?

The present position of the question as to the presence of a trace of sugar in normal urine may be briefly stated. Some eminent chemists and physiologists obtain from the urine a substance which has all the characters of glucose; but the

question arises, Does this substance pre-exist in the urine or is it an artificial product of the processes employed for its extraction? This question has not been answered, and it is one which it will be extremely difficult to answer satisfactorily; but surely Dr. Pavy should be the last to deny the possibility that a carbohydrate may be split off from some constituent of normal urine, since throughout his work on "The Physiology of the Carbohydrates" he repeatedly asserts that all the tissues and organs of the animal system are "glucosides," from which by a "cleavage-process" sugar may be separated. Thus by boiling with acids or alkalis he separates sugar from muscle, from beef-tea, from the white and yolk of egg, and from various other proteids. It is remarkable that in Dr. Pavy's book there is no mention of two almost ubiquitous cupric oxide reducing substances, kreatine and kreatinine. It is certain that a portion at least of the reducing action of such a tissue as muscle or such a liquid as blood must be due to one or both of these bodies, yet there is no indication that Dr. Pavy, being aware of this source of error, has been careful to guard against it. The fact that his estimate of the amount of sugar in normal urine is about five times greater than that of the German observers Baisch and Seegen is unquestionably explained by his ignoring kreatinine and attributing to glucose the entire reducing action on cupric oxide which occurs after the removal of uric acid.

The question of the presence of a trace of sugar in normal urine is one of little or no practical importance; but I have the satisfaction of knowing that by the picric acid test, employed as I have described in my last paper,¹ I can with the greatest ease and certainty detect the smallest trace of sugar which has any clinical significance. Let me remind your readers that there are two classes of facts which appear to be inconsistent with the presence of sugar in normal urine: (1) the fact discovered by my son that, after the separation of uric acid and kreatinine by the mercuric chloride process, which does not remove sugar, the filtrate is found to contain no trace of a reducing agent; (2) the experiments described in my paper prove that the entire picric acid reduction² of normal urine is accounted for by the kreatinine contained therein. In no specimen of normal urine have I found a trace of sugar, but I have a dyspeptic friend and patient now seventy-one years old whose urine during the last ten years has occasionally contained sugar varying in amount from one to three grains and a half per ounce. With strict attention to diet he is now apparently in good health, but, thinking it probable that the urine might still contain a trace of sugar, I lately asked him to send me a sample. The specific gravity was 1023. Boiled with picric acid and potash, the reduction colour indicated one grain per ounce, calculated as glucose. The reducing power of kreatinine being less than that of glucose in the proportion of 10 to 12, a solution of kreatinine in the proportion of 1·2 grain per ounce gave the same depth of colour as the urine. When the two liquids, the urine and the solution of kreatinine, were tested after their dilution had been carried beyond the point (one grain in 10,000 minims)³ at which glucose ceases to exert any reducing effect upon picric acid, the urine was visibly paler than the kreatinine solution; and in order to equalise the colour of the two liquids one-fifth of its volume of water was added to the solution of kreatinine in a small graduated tube of the same diameter as that which contained the urine. This analysis shows that 0·8 of the picric acid reduction was due to kreatinine, this being the average amount in normal urine, and 0·2 to glucose. This amount of glucose, one-fifth of a grain per fluid ounce, thus easily determined, is slightly less than Dr. Pavy declares to be present in normal urine. This simple but accurate method of analysis has been rendered possible only by my son's success in separating and obtaining in a pure state the unchanged urinary kreatinine. This work of his, which has hitherto been strangely neglected, will, I venture to say, be soon acknowledged to be the most important contribution to urinary analysis that has been made within the last ten years.

In the numerous communications on the subject of urinary tests which during the last twelve years the Editors of THE LANCET have done me the favour to publish I have had in view two main objects. First, to prove that in picric acid

we have an invaluable quantitative as well as qualitative test for both albumen and sugar. In the pursuance of this object I have from the first had to meet the strenuous opposition of Dr. Pavy with some other opponents of less note.⁴ My second object has been to impress upon the profession the duty of testing the urine of every patient and of every applicant for life insurance.

A few weeks before the death of Sir William Gull, during an interesting half hour's chat with my old friend, though an occasional opponent, he said to me, "You know the true interpretation of *γνώθι σεαυτὸν* is *test your urine*." If every member of the profession would systematically act upon this maxim the result would be that fewer cases of insidious latent disease would remain undiscovered until they have passed into an incurable stage.

I am, Sirs, yours faithfully,

Savile-row, Feb. 12th, 1895.

GEORGE JOHNSON.

To the Editors of THE LANCET.

SIRS,—A transposition of some words in the last paragraph of my letter inserted in your last issue has occurred, whereby a portion of it has been rendered unintelligible. May I ask you, therefore, to make the correction? It refers to von Baisch's statement; and should run as follows: "The existence of sugar in normal urine is susceptible of demonstration by the polarimeter, by Fehling's solution, by the production of glucosazone, evidenced by crystalline form, melting point, and composition, with phenyl-hydrazine, and by fermentation with yeast with the formation of alcohol." Dr. Halliburton has now entered the discussion, and I seek permission to comment upon what he has said. Carrying on the figurative allusion introduced into last week's correspondence he may be spoken of as having undertaken the *role of advocatus Dei*. Let us see whether in this *role* he displays that soundness and clearness of judgment and impartiality upon which he has justly attained so high a reputation in his physiological writings.

Dr. Halliburton begins by misquoting me. This from him I am much surprised at. He says: "I find, however, on referring to p. 181 of his book that the material he operated on was strongly acid and did not ferment with yeast till rendered alkaline with sodium carbonate." I do not state "rendered alkaline." What I do state is "neutralised," and this makes all the difference in relation to the subsequent remarks of Dr. Halliburton on the suggested effects of the presence of sodium carbonate. Turning to my original writing,¹ which is referred to in my book as the basis of my text, brought to a neutral state is the form of expression used. I am constrained here to reproduce what follows about the testing of the neutralised product, as, although written nineteen years ago, it falls appositely into the present discussion and forcibly speaks to the point. "With the product in my possession, procured from healthy urine, I can now show a good reaction with all the tests I have referred to. At the meeting of the Royal Medical and Chirurgical Society of Nov. 23rd, 1875 I exhibited a specimen of the product and applied the various tests before the Fellows present. Moore's test gave a dark brown colouration; the bismuth (Böttger's) test became black; the copper solution gave a copious precipitate of orange yellow reduced oxide; and the fermentation test acted briskly. The process of fermentation was allowed to proceed during the course of the meeting, and at the end of the evening the evolved gas was shown to consist of carbonic acid by the absorbing action of potash, and further the fermented liquid was submitted to distillation and the distilled product allowed to fall into a solution of chromic acid in sulphuric acid, when the change to green, indicative of the presence of alcohol, was obtained."

I referred in my last letter to Sir George Johnson's suggestion about evolved carbonic acid from sodium carbonate by the action of an acid being open to being mistaken for that evolved by fermentation. In the hands of a competent person, and with proper evidence of fermentation afforded, it is utterly impossible for the mistake to be made. The evolution of gas from fermentation does not begin to any significant extent until a supposed evolution from sodium carbonate would have been long over. It then goes on increasing in briskness, so that after, say, half or three-quarters of an hour at a temperature of 90° to 100° F. an

¹ THE LANCET, Jan. 12th, 1895.

² Uric acid which reduces cupric oxide has no reducing action on picric acid.

³ See my paper before referred to.

⁴ See THE LANCET from November, 1882, to December, 1884.

¹ "On the Recognition of Sugar in Healthy Urine," Guy's Hospital Reports for 1876, p. 421.

Infinitely greater amount of activity is observable than previously.

Dr. Halliburton has advanced upon the position taken by Sir George Johnson, and from simply one set of experiments makes bold to suggest, in opposition to all previous knowledge, that yeast has the power of splitting asunder the acid and base of sodium carbonate and leading to the evolution of the former in the form of gas. As an alternative explanation he suggests that the yeast itself may have contained some sugar which was decomposed by the cells in a medium containing sodium carbonate, but he declares himself for the present to be rather inclined to adopt the former hypothesis. I have repeated Dr. Halliburton's experiments without obtaining the slightest corroboration of his proposition that sodium carbonate is responsible for the evolution of gas in the presence of yeast, which is what Dr. Halliburton wants to prove; and I affirm that sodium carbonate is quite the proper thing to use as a neutralising agent under the circumstances. But, as far as my application of the fermentation test to the extracted sugar from healthy urine was concerned, the ground of objection raised by Dr. Halliburton did not exist owing to the fact that virtually there was no sodium carbonate present, the addition of it only having been carried to the point to attain neutralisation. Dr. Halliburton says nothing about having taken the precaution to wash his yeast previous to employment. There is always a certain amount of fermenting impurity present. This doubtless constituted the essential factor connected with his results. Withal, however, there is a want of consistency about them, and to base such a proposition, as Dr. Halliburton has done, upon the few experiments he only claims to have performed is nothing short of an offence to true science. Would Dr. Halliburton have introduced the crude material he has sent to you into his scientific writings? If he reply in the affirmative, all I can say is that with procedure upon such lines it would not, I am of opinion, take long for the good reputation he now possesses to vanish. I ask, then, is Dr. Halliburton to consider himself at liberty to serve up material to you for the medical profession that I venture to think he would not bring forward at any scientific society or introduce into any scientific writing? Notwithstanding the position he has taken, Dr. Halliburton before finishing, admits that he thinks there is enough to convince the impartial observer that a small quantity of glucose is obtainable from normal urine. What more than this is wanted? It is all in reality that I have throughout contended for. Sir George Johnson has based arguments upon the *quantity* he says I have asserted to be present. I have not, however, committed myself to anything absolute upon this point. My statement contains the provisional "if" to meet the doubt that existed in my mind. It runs thus: "If the cupric oxide reduction found to occur [after treatment with the neutral and basic lead acetates] be read off as produced entirely by sugar, the amount of this principle ordinarily existing in healthy urine may be said to stand at about 0.5 or a little over per 1000." 0.5 per 1000 would only give about two-thirds of a gramme, or about ten grains, as the average elimination for an adult subject in the twenty-four hours—a quantity that cannot be looked upon as *per se* having any importance. As long as only Sir George Johnson quoted me imperfectly I did not consider it necessary to take any notice, but Dr. Halliburton at the end of his letter falls into the same imperfect representation. Hence the explanation I have given.

Grosvenor-street, Feb. 13th, 1895.

I am, Sirs, yours faithfully,
F. W. PAVY.

To the Editors of THE LANCET.

SIRS,—I am obliged to Sir George Johnson for explaining some of the points respecting which I, doubtless in common with other of your readers, had misunderstood him. I certainly thought that the confusion of grains per 100 minims with the "percentage weight of sugar to the volume of urine" was due to inadvertence; but now that Sir George Johnson maintains that the expressions are practically identical I must point out the distinction. "Percentage weight in volume" will be understood by most people to mean the number of grains weight of a substance contained in 100 fluid grains of a solution, or in the metric system the grammes of substance per 100 cubic centimetres. But Sir George Johnson applies the term to *grains weight per 100 minims*—that is, to the number of grains per 91.1 fluid grains. Probably Sir George Johnson will be

alone in applying the term "percentage" to this curious relationship. But Sir George Johnson is not even in agreement with himself on the matter, for, while he gives the divisor 4.8 in his recent paper, in the directions issued with his picro saccharometer the correct divisor, 4.375, is directed to be used. Of course I at once accept Sir George Johnson's assurance that he lays stress on the presence of urinary sugar even in the smallest traces, but I feel bound to show how I came to misunderstand his views. In the directions issued with his apparatus it is stated that if the colouration produced is less than the standard the urine is either free from sugar or contains less than one grain per fluid ounce, and that all normal urines reduce picric acid and produce a colouration to a variable extent, ranging from that corresponding to 0.5 up to 1.2 grains of glucose per fluid ounce. It is evident that in presence of an unknown and variable proportion of kreatinine, itself liable to produce a colour corresponding to more than one grain per ounce of glucose, it is quite impossible to estimate small quantities of sugar, or even to detect them. Of course, if the kreatinine be first removed, by Mr. G. Stillingfleet Johnson's or other method, the chief cause of obscurity is removed, but the test thus compulsorily modified does not bear out Sir George Johnson's statement that "for the clinical observer the presence or absence of glycosuria may be decided in about two minutes," "no other method of testing for glycosuria equalling this for the ease and rapidity with which it may be conducted, and for the absolute trustworthiness of the result." I am not traversing the convenience and value of the picric acid test for detecting and roughly estimating sugar in typical cases of glycosuria. As stated in my last letter, while the results are amply sufficient to allow of a judgment as to the progress made by a diabetic patient, they are quite inconclusive as evidence on the vexed question of the presence of traces of sugar in normal urine. As to the liability of picric acid to yield a more or less reddish solution when boiled with liquor potassæ (B.P.), I can only repeat that my experience is at variance with that of Sir George Johnson, and it would be interesting to learn whether the behaviour mentioned by me has been observed by other of your readers.

I am, Sirs, yours faithfully,

Surrey-street, Sheffield, Feb. 11th, 1895.

ALFRED H. ALLEN.

"THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—Having given Sir John Williams and Dr. Playfair an opportunity for further explanation, and having noted that neither of them have made use of it, it appears to be an opportune moment to call attention to a few points. Dr. Playfair speaks of the high motives of the Obstetrical Society and the success of the examination. Sir John Williams advances as an argument against the recent action of the General Medical Council that all the obstetric physicians of note are contingently branded with infamy. He further states that none are better able to train and examine midwives or are better informed of the needs of the poor in their travail. Now, however high motives be, men of the highest respectability and position may be mistaken in the means they adopt to attain their end. The regulations for these examinations, for instance, do not compel the candidates ever to have attended a lying-in woman during the puerperium, and the examiners have gone on examining year after year and have not detected the fact that some women (how many is not known) who have passed the ordeal of examination with success have not done so. That the successful candidates themselves are admittedly ignorant of the rudiments can be shown by the fact that a printed circular was recently sent to the successful candidates warning them that they ought not to undertake cases if they were suffering from such troubles as *ozæna*, suppurating sores, or necrosis of bone. This certainly appears to be a practical acknowledgment of the fact that candidates who are given the diploma which is the cause of the trouble are not to be trusted. To encourage such women to practise amongst the poor may be considered by some to be in the interests of humanity, but because others do not do so there is no obvious reason why their representations should be unheeded. Representations have been made to the effect: 1. That on the Continent, where midwives practise midwifery under strict State control, the

following results are observed—(a) the lowest mortality amongst the lying-in is 5.4 per 1000, the highest 12.3 per 1000, that in our own country being about 4.5; (b) the system has not resulted in removing the unqualified practitioner from the poor, who practises as she does in this country; (c) the midwives do not, as a matter of fact, although required to do so by law, send for the surgeon for the repair of the perineum—in fact, they do not send for medical assistance unless compelled to do so in extremity. 2. That although the Obstetrical Society has over 2000 midwives on its books, these persons are not found to be generally practising amongst the poor unless employed by institutions or charities. 3. That certified midwives have been found guilty of criminal practices.

I will now call attention to the case of the certificated midwife, mentioned in THE LANCET of Feb. 9th, as showing some of the dangers which are likely to be the result of the action of the Obstetrical Society. It appears to me that the obstetricians of note, so far from promoting the interests of humanity, with the best intentions in the world, have done and are doing just the reverse. The Royal College of Physicians of London cannot escape some responsibility in the matter. Just before the meeting of the Select Committee of the House of Commons it issued a report on the subject of midwives' registration. The medical profession, no doubt, knowing the propensity of the College for being at least a quarter of a century behind the times, did not pay much attention to it, but it carried weight before the Select Committee. In this report allusion is made to the fact that in Continental countries midwives practised under State control. The College could not be expected to ascertain the results obtained under such a system; indeed, there was no information available relating to all foreign countries until the return on stillbirths was published, and, as Dr. Farquharson admitted when I was giving evidence before the Select Committee, their committee could not be expected to sit more than two or three times. It could not in view of the composition of the committee and the old-world ways of the College, but it does not follow that a reasonable conclusion could possibly be arrived at by such procedure. If accoucheurs of note will kindly enlighten our darkness on any or all of these points I am sure they will delight an admiring profession, which at present fails entirely to see the reasonableness of their course of action.

I am, Sirs, your obedient servant,
Hatfield, Feb. 10th, 1895. LOVELL DRAGE.

"THE DENTIST'S EDUCATION."

To the Editors of THE LANCET.

SIRS,—The examination of candidates for the L.D.S. of the Royal College of Surgeons of England has long been a grievance with dental teachers. Beyond the introduction of the "practical" portion in 1879 no other improvement of any moment has taken place in the examination since 1872, when written papers were given in addition to the *visu-voce*. All the other licensing corporations—Edinburgh, Glasgow, and Dublin—have their primary and final examinations at two periods of the dental student's career. But in this matter the Royal College of Surgeons of England remained stationary, apparently fixed, notwithstanding the utterances of teachers and others, many times repeated from 1879, urging that the examination in the general subjects of the curriculum—at all events, anatomy and physiology—be taken at a different time from that of certain of the special subjects—dental surgery &c. Not only would such a division of the examination reduce the tendency to "cram," which the existing single examination in all the subjects fosters, but the onus of preparing the candidates in anatomy and physiology would rest upon the teachers of those sciences at the general medical schools and not, as heretofore and at present, upon the tutors of the dental schools—a preposterous anomaly which ought not to exist. Regarding the question of adding another—a third—year to the hospital portion of the dental curriculum referred to by Mr. Newland-Pedley in THE LANCET of Feb. 2nd I shall not discuss it now; but I would emphasise this fact, that the marked superiority of the British over the American dentist's education has hitherto consisted in the better theoretical groundwork and knowledge of the former. Our "cousins" are, however, advancing in this respect and that markedly, and if we are to maintain that higher standard the Royal College of Surgeons of England—the licensing corporation that admits to the pro-

fession the majority of the recruits—should not lose any more time in effecting improvements in the nature and scope of its dental examinations.

I am, Sirs, yours faithfully,

THOMAS GADDES,
late Dean of the National Dental College, London,
and also of the Dental Department of the
University of Denver, U.S.A.

Harrogate, Feb. 6th, 1895.

"THE DEBATE ON THE NATURE AND TREATMENT OF PERITONITIS AT THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—As the author of the paper which has been the occasion of such lively correspondence the last two or three weeks, will you grant me space for a few remarks? Nothing impressed me more at the debate than the antagonism of the views advanced by different speakers even on a mere question of fact; whether, for example, a certain case was or was not a case of peritonitis. The letter of Mr. Emmett in your last week's issue has, to my mind, the right ring about it. The mortality in his obstetric practice, from conditions which he had been wont to regard as due to peritonitis, has diminished since his adoption of the purgative treatment to the vanishing point. My advocacy of the employment of purgatives in peritonitis rests apparently on entirely different grounds from those maintained by Mr. Lawson Tait; but whether one theory or the other, or neither, is correct matters, after all, but little. Truth is not absolute and final, much less can the statement of a truth be. Let the profession put the treatment advocated to a practical test. For the other suggestions in my paper I do earnestly beg the like consideration. Firstly, the regular washing out of the stomach until the bowels can be got to act; secondly, the support of the heart strength and kidney activity by the administration of strychnia and digitalin; and, thirdly, inhalations of oxygen with the object of increasing the oxidising power of the blood.

I am, Sirs, yours obediently,
Queen Anne-street, W., Feb. 11th, 1895. JOHN SHAW.

To the Editors of THE LANCET.

SIRS,—Many, like myself, are grateful to the man who has helped us so much to bring our abdominal operations to a successful termination. It seems to me that it is a very small and cheap notoriety that is to be obtained by attacking a man on what Mr. Richard Emmett well describes as a verbal quibble. Surely Mr. Lawson Tait may be allowed to treat such attacks with contemptuous silence. We all know perfectly well what Mr. Tait means when he says that the removal of distension prevents peritonitis, and if he has at some time expressed this in terms which might lend themselves to a different construction it ill becomes anyone to be continually carping at him. It is not too much to say that many hundreds of lives have been saved by the adoption of Mr. Tait's purgative treatment of distension, and that abdominal surgery owes its position to-day in a great measure to his boldness and teaching.

I am, Sirs, yours faithfully,
Huddersfield, Feb. 13th, 1895. T. KILNER CLARKE.

THE TREATMENT OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—I observe that in the comparisons now being drawn between the results of the antitoxin treatment of diphtheria and those obtained by the old methods the writers have referred to only two remedies as being used in combating the disease—namely, the perchloride of iron and chlorate of potassium with hydrochloric acid. I have seen no mention made of a preparation which in my hands has had a marked effect in arresting the exudation of membrane on the fauces. I allude to the euechlorine solution first employed as a remedy for scarlatina anginosa and enlogised by Sir Thomas Watson in his lectures on the Practice of Physio. For more than twenty years I have used the solution, made according to the formula given in the lectures, in cases of diphtheria, and I may say with a success nearly comparable to that obtained with antitoxin serum in the metropolitan hospitals. In fact,

the only instances of its failures I can remember were complicated with laryngeal and tracheal effusions or were primarily cases of membranous croup. It always appeared to me that this solution, which is a most powerful antiseptic, has both a topical and general effect in neutralising the diphtheritic poison, as it not only hastens the detachment of membrane from the throat, but it appears to lessen the chances of secondary affections, whether in the form of paralysis or renal incompetence. But for these effects to be obtained it is necessary that the solution should be freely and frequently administered, so as to keep the fauces as nearly as possible aseptic. And with the same view I have always used sulphurous acid or solutions of carbolic acid either as a spray or to swab the throat with. My estimate of the value of euclochine in diphtheria is supported by the testimony of Mr. T. Schollick, who was for several years medical officer of the Isolation Hospital for this union, and who had opportunities of testing its effects during more than one severe epidemic of this disease. It may seem late to propose a remedy for diphtheria in the face of the remarkable results obtained by the use of antitoxin, which possesses the advantage of controlling the laryngeal and tracheal affections, so often a cause of fatality. But circumstances may even yet arise to render a substitute for the serum a not unwelcome addition to our resources.

I am, Sirs, your obedient servant,

Guildford, Feb. 5th, 1895.

HENRY TAYLOR.

"ENUCLEATION OF HYDATID CYST OF LIVER."

To the Editors of THE LANCET.

SIRS,—While congratulating Mr. Morgan on the satisfactory result in the case of hydatid cyst of the liver published in THE LANCET of Feb. 9th, I am anxious to draw attention to a method of treating these cases which I believe to be an advance on that followed in Mr. Morgan's case. In a paper published in 1891,¹ and again in January this year, I explained the method of treating all cysts which are not suppurating by incision, evacuation of the contents, and parasitic cyst only, and closure of the abdominal wound without drainage. By simply removing the daughter cysts and the parasitic endocyst, which has no organic connexion with the adventitious cyst, and by not making any attempt to remove or separate from surrounding parts the latter fibrous investment, the danger of hæmorrhage is entirely avoided. No doubt some omental cysts can be removed with the fibrous cyst entire, but this should not be attempted in liver cysts. Although this method seems after four years to be but yet little practised in England, it has been extensively adopted in Australia, and from your Australian Correspondent's account of the Medical Society of Victoria's meeting, reported in THE LANCET of Feb. 9th, it would appear, successfully. No doubt it is not always necessary, except in the case of very large cysts, to invert and suture the adventitia as I originally suggested; neither is it, I think, desirable to anchor the evacuated cyst to the parietal peritoneum, as advocated by some Australian surgeons, unless any accidental contamination should have occurred at the operation.—I am, Sirs, yours faithfully,

King-street, Leicester, Feb. 11th, 1895.

C. J. BOND.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—I desire to make an appeal to the profession on behalf of Mrs. Julia Guthrie, who is a widow of the late Professor Guthrie, at one time President of the Royal College of Surgeons. Mrs. Guthrie was married at St. Ann's, Soho, early in 1856, and was left a widow in that year with one son, who has since died. Mrs. Guthrie was left on the death of her husband unprovided for, but the son was during his lifetime assisted by members of the family. For many years Mrs. Guthrie has been dependent upon her relatives, who have now all died, and she is left alone in the world. A few months ago I was instrumental in obtaining a pension of £18 per annum for Mrs. Guthrie from the British Medical Benevolent Fund, which at the present moment is sufficient to pay for her one room. It is desired to make a provision for her life of the very moderate sum of £1 per week, and as Mrs. Guthrie is nearly seventy-five

years of age I confidently appeal to the profession to assist in this charity. An account has been arranged at the Capital and Counties Bank (head office, Threadneedle-street, E.C.), and any subscription can be paid to them to the "Guthrie Relief Fund" or to the honorary secretary, Mr. R. Brandreth, L.L.D., solicitor, 2, Duke-street, Brighton, of whom any further particulars of Mrs. Guthrie's sad case can be obtained.

I am, Sirs, yours obediently,

ALFRED UPTON, L.R.C.P. Lond., M.R.C.S. Eng.
Lansdowne-place, Hove, Brighton, Feb. 13th, 1895.

"FILARIA LOA."

To the Editors of THE LANCET.

SIRS,—With reference to the filaria loa described in THE LANCET of Oct. 27th, 1894, supposed to be found only in Africa, I would mention the following case. A few weeks ago a horse was brought to me with a filaria moving rapidly about in the ante-chamber of its left eye. The filaria appeared about an inch and a half long, tapering at one end, blunt at the other. I ordered some perchloride of mercury solution to be injected through the cornea to kill it. Unfortunately for the specimen, but fortunately for the horse, when the aqueous escaped through the puncture the filaria also wriggled through, fell on the ground, and was lost, as I was not informed of the result in time to search for it.

I am, Sirs, yours faithfully,

Mission Hospital, Kashmir, Jan. 7th, 1895.

ARTHUR NEVE.

THE MEANS OF CULTIVATING ORGANIC REACTIONS IN AIR AND THEIR RELATION TO ZYMOTIC DISEASE.

To the Editors of THE LANCET.

SIRS,—The indefinite nature of recorded research due to the natural difficulties of demonstrating the facts involved in atmospheric pollution by sewage is exemplified in the following statement made at a recent meeting of the London County Council regarding sewer gas in London. The Main Drainage Committee had the subject under consideration, and when they learned from the experts that sewer gas was free from germs they were very much astonished. They had, however, referred it to the experts to say whether sewer gas was not injurious to public health "in some way" other than through the presence of bacilli. The evidence available in proof of pathogenic origin in organic reactions in air as yet is more valuable in its indications than in actual facts. The effects, however, of organic pollution in air were early noticed by me during very protracted experiments in aerifying sewage and other liquors between 1878 and 1886. These effects, regarded as distinct from odour, were always apparent during the treatment of sewage in any stage of putrefactive ferment, and as possessing a distinct bearing on a subject which I believe requires investigation on its own account.

The first actual evidence of pathogenic origin in air is supplied by the result attending the influenza inquiry instituted by the Local Government Board. It is simple history that a subsequent official inquiry by the Board attributed the malady chiefly to the presence of refractory organic impurities in the air. It was now apparent that the march of events by investigation must soon supply the corroborating details which I felt were required to clearly indicate the direction and means by which a real demonstration of the facts might be conveniently obtained. These details were furnished in the highly important conclusions advanced by Dr. Percy Frankland, F.R.S., dealing with the subject at last year's Congress of the British Association at Nottingham, which, I venture to think, afford the clue to the ultimate results of phenomena described, and also, short of demonstrating the facts, define the modification influence which operates in nature through organic reactions in air. The following quotation from Dr. Frankland's address on Bacteriology at the Congress of the British Association in 1893 contains the conclusions referred to:—1. "The science of bacteriology dates from the introduction by Koch of the method of pure cultures some twelve years ago. Microscopical determinations, at first entirely relied upon, had given way more and more to chemical tests, but the differentiation and identification of 'particular species' remain very difficult, and, indeed, become more and more so." Comment is needless, beyond asking the question, Why, unless a modifying

¹ Brit. Med. Jour., April 7th, 1891.

influence expands in sympathy with ever-increasing volume of putrefactive sewage, should identification of "particular species" remain with experience very difficult, and, indeed, become "more and more so"? 2. "By educational culture the character of an organism may be quite changed. On the other hand, the virulence can be increased, although as yet no pathogenic organism 'has been raised' from non-pathogenic, but as 'similar modification processes' evidently go on in nature we must grant that bacilli acquire new characteristics under new conditions." The question here is, Does chemistry or nature itself in other direction afford us the study of similar conditions to those prevailing in sewers? If not, we must admit that organic life exposed to such influence must adapt its function to surroundings. How this adaptation works is the very essence of the actual demonstration required. 3. "We have real anthrax and an exceedingly similar innocuous modification, both occurring in the soil. Many toxic forms—cholera, typhus, diphtheria bacilli—have pseudo-forms. In certain cases the modification may be due to the exclusion or exhaustion of oxygen. Assuming fermentation in presence of air to be normal, as in the early days of Pasteur, a modified reaction can apparently proceed when no more oxygen is at disposal, so that we have also anaerobic fermentation." We have here the modification influence defined, and also the answer to both the questions asked; whilst, as regards the influence exerted by organic impurity in air, we find that all available evidence supports the view that an actual demonstration of facts of the first importance to the medical profession and the public at large is alike possible and much to be desired.

In recent experiments made with a special form of apparatus suggested by results described I have, I believe, secured the means of convenient observation of sewage reactions in every form, produced under precisely the same natural conditions which operate in town sewers under variable conditions of time, temperature, and air-supply. As regards the practical aspect, since the introduction of Koch's method of culture I have held the belief that by securing control of the nature of fermentation in sewage we secure the only effectual means of reducing that organic pollution of the atmosphere of populations which all available evidence proves the public interest demands. This control I have secured by means of halogen disinfection through the medium of air-supply. It will be remembered that similar means are relied upon to secure the disinfection of organic emanations escaping at manholes, &c., connected with the system of the London main sewers. In that case sulphurous acid is, I believe, the agent employed; the cost, however, in perhaps all other cases is prohibitive. On the other hand, by using the sulphurous vapours (given off by the storage batteries used in electric supply), in conjunction with air and complete removal of the volatile by-products of sewage, we obtain effectual control over the fermentive course, even with fluctuations in the amount of organic matter as high as 800 per cent. The fluctuations in London are doubtless of much wider range and serve to show the futility of relying on any practicable degree of aeration sufficient to meet the necessities of the case in which the oxygen required for normal course may vary in an hour between two and ten or even more grains per gallon. In such fluctuations as named we probably see the first cause of putrefactive ferment in town sewers, which ends in producing influences under which we must grant that bacilli acquire new characteristics. It is equally probable that with exhaustion of oxygen a modification begins by which the normal functions of organisms become changed. Pathology has taught us much regarding the life history of germs attending specific forms of disease, but the question still remains, How come these disease germs into existence? I am, Sirs, yours faithfully,

Sheffield.

J. HILL-HARTLAND.

* * We publish this letter in view of the interest of this subject, but we have been compelled to reduce the great length of the original communication.—ED. L.

"THE REMUNERATION OF THE RESIDENT OFFICERS OF ST. BARTHOLOMEW'S HOSPITAL."

To the Editors of THE LANCET.

SIRS,—If you will kindly allow me a little space I should like to reply to your correspondent "Fair Pay" in the

matter of his letter about the pay of the resident officers at St. Bartholomew's. What are his facts: (1) the residents get £25 per annum; (2) during the six months they are in residence they have to pay for their food. These are perfectly correct, but "Fair Pay" might remember that wages or salary are regulated by the laws of supply and demand. There is no doubt that even if the residents had to pay a fee for holding the resident appointments there would be no lack of candidates, so that under the present régime there is something to be thankful for.

Now I am certain that no one who has been on the junior staff of St. Bartholomew's will deny that the experience he gained, and, to use a colloquialism, the general good time he had, were worth far more than the £50 which he spent on his food. Whether he were in the service of the hospital or not, he would have to eat, for the average man out of whom a resident officer is made is of coarser mould than Eve Níegen, the lady who lived on the smell of flowers. Finally, if "Fair Pay" has anything to do with St. Bartholomew's, why does not he say so? If he has not, he appears to be interfering in a matter which cannot concern him—unless, indeed, he is the parent of a house physician or surgeon.

I am, Sirs, yours faithfully,

AN OLD HOUSE SURGEON OF ST. BARTHOLOMEW'S.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Recent Severe Weather.

THE severity of the frost here may be judged by the appearance of ice in the Mersey. Fourteen years ago the river was in parts frozen over, a most unusual sight, and again has this sight been witnessed. The training ships have been as icebound as if they had been in Arctic regions, and ferry steamers have had to plough their way through the ice. As many as 15° F. of frost have been registered in the city itself, while in the suburbs an even lower temperature has been reached.

The Medical Charities.

During the months of January and February the annual meetings of all the medical charities are held. These all show a continuation and aggravation of the state of chronic bankruptcy into which our hospitals and dispensaries are permitted to languish. The Royal Infirmary owes its bankers £3000, the Northern Hospital owes £4000, and the Royal Southern Hospital has a balance on the wrong side of £5000. Thus a total of £12,000 will be required to free these three institutions from debt, and then the struggle between an insufficient income and a heavy expenditure will begin again. Out of the half million inhabitants of this city not more than ten thousand at the very most are annual subscribers to the medical charities. A prominent citizen remarked at the annual meeting of the Royal Southern Hospital yesterday that with a few honourable exceptions the shopkeepers did not support the charities as they deserved, and from what has just been stated it must be obvious that there is plenty of room for improvement.

The Lord Mayor and the Hospitals.

The Lord Mayor (Mr. Watts) has shown his interest in the various hospitals, not only by presiding at the annual meetings (except at the Royal Infirmary, when Lord Derby presided), but also by visiting them. In addition to the hospitals already alluded to his lordship has visited the Hospital for Consumption and the Liverpool Eye and Ear Infirmary. These visits from the chief magistrate are very greatly appreciated.

Salting the Streets: the Removal of Snow and the Unemployed.

The question as to whether the salting of the streets after snowstorms is or is not a desirable practice has again come to the fore. On the one hand, it is contended that it is cruel to horses and barefooted persons, and also to the public generally, since it intensifies the coldness of the atmosphere. It is urged, on the other hand, that in such a city as this, with 300 miles of streets, it would be impossible to remove the snow in any other way. The usual scavenging staff was augmented by casual helpers, but only a very small proportion of the number required applied out of the alleged large number of unemployed. It is to be feared that too many of these men prefer idling and hawking their grievances in the streets to honest efforts to obtain work, forgetting or ignoring that such conduct may end in a reappearance of typhus fever.

The Alleged Compulsory Vaccination of Liverpool Firemen.

A paragraph appeared in the local papers stating that a fire had taken place at the Small-pox Hospital and that all the members of the police fire brigade who were present had to submit to compulsory vaccination. In consequence of this Mr. Hopwood asked the question in the House of Commons of the Parliamentary Secretary of the Board of Trade on Tuesday last. Sir Walter Foster answered that there was no compulsion, nor could there be. The idea of forty or fifty policemen being compulsorily vaccinated by the resident medical staff of a hospital would be ludicrous to anyone except the learned recorder of Liverpool, whose sense of the humorous is absorbed in his chronic horror of compulsion. The hospital had at the time cases of small-pox more or less severe, some of the firemen had never been vaccinated since infancy, none had been done recently, and many fully intended being vaccinated in accordance with the suggestion of the Watch Committee, noticed in THE LANCET of last Saturday, p. 352. To have permitted these men to return to their homes from an infected centre without strongly urging the best protection which they could have would have been gross neglect on the part of the hospital staff. All the men's arms have taken extremely well; not one has been infected with small-pox nor have incurred any ill-effects beyond those incidental to vaccination, and many members of the police force are availing themselves of the opportunity afforded to them of being revaccinated.

Feb. 13th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Durham.

DEAN KITCHIN has come into residence, and as warden is taking a very active interest in all that concerns the University. A scheme of extension lectures, among other undertakings, has been elaborated for the benefit of the northern counties, in which the professors in the various faculties at Durham and at Newcastle are all to participate, so that there is hardly any subject, literary or scientific, which will not be dealt with. The scheme is an ambitious one, but there is every reason to believe that it will be successfully carried out and fully appreciated.

Newcastle-upon-Tyne Royal Infirmary.

The annual meeting of the infirmary governors was held on Feb. 7th, when the reports for the past year were read. The expenditure has exceeded the income by £3000, due chiefly to a falling off in contributions and dividends. The average cost of each in-patient has been £4 0s 11d., and the gross cost of each occupied bed £52 16s. 0d. The medical report is a satisfactory one, showing a considerable increase in the number of patients treated in all departments. 1754 operations were performed. The abdomen was opened 155 times and 29 patients died. The kidney was removed 4 times with 1 death. Ten cases of stone in the bladder were treated without a death. Sixty-eight operations were performed for the radical cure of hernia with 1 death, and 14 for strangulated hernia with 3 deaths. Phelps's operation for club-foot was performed 6 times with most satisfactory results. There were 68 major amputations with 8 deaths, all but one within a few hours from shock and loss of blood; one occurred from pyæmia, the patient being septic on admission and at the time of operation. There were 25 excisions of joints without a death. The staff call attention to the want of a new infirmary in the following terms:—"The work of the infirmary is each year carried on with increasing difficulty. The house is old and inconvenient. The accommodation for in-patients is inadequate. The out-patient department is as bad as it can be. There is not living room for the staff of nurses in the building. All these and other defects render the administration difficult and expensive, and emphasise the resolution passed by the governors at the last annual meeting that a new hospital, on another site, is urgently required. The staff are unanimous as to the site on which a new infirmary can be built most advantageously."

University of Durham College of Medicine.

Messrs. Hargreaves and Joblin, trustees of the estate of the late Professor Johnson, some time Professor of Chemistry in the University of Durham, have generously presented the

sum of £200 to the College of Medicine for the purpose of providing additional physiological instruments.

Newcastle-upon-Tyne Lying-in Hospital.

The annual meeting of governors of this charity was held in the hospital, New Bridge-street, on Jan. 30th, the Rev. J. Wilkinson, vicar of St. Peter's, being in the chair. The report of the committee showed a large increase of both in- and out-patients during the past year, 348 women having received the benefit of the charity. The treasurer's report showed a slight falling off in the annual subscriptions in 1894, but the year closed with a balance of £13 12s. 2d. to the credit of the charity. A vote of thanks to the chairman concluded the proceedings. The credit of the good financial position of the above charity is due mainly to the business capacity of Mr. Neatham, the honorary secretary.

The Medical Defence Union, Limited.

A meeting of the profession was held on Feb. 7th in the council chamber of the University of Durham College of Medicine. Professor Arnison, one of the vice-presidents, was in the chair. Mr. Victor Horsley pointed out the objects of the society and the claims for support it had upon the profession. In the course of his remarks he said the society would like to undertake the prosecution of quacks, but that it had not the means wherewith to do so. He suggested that the British Medical Association, out of its large and yearly increasing surplus, might be able and willing to give of its abundance a substantial donation to the Defence Union for this purpose. It was agreed by a large majority to refer this question to the Northern Branch of the British Medical Association for consideration. The determination was not arrived at unanimously. A prominent member of the British Medical Association expressed his opinion that it was undesirable for the two associations to be associated, and advanced arguments in which there is undoubtedly much force.

The Newcastle-upon-Tyne Clinical Society.

This society held an extraordinary meeting in the Medicine Theatre of the College of Medicine on Feb. 7th. The President, Professor G. R. Murray, occupied the chair, and introduced Mr. Victor Horsley, who delivered a most interesting and instructive lecture to a large and appreciative audience on Oxydisation in the Tissues. The lecture was illustrated by an experiment and by lantern slides. In the evening the annual dinner was held in the Hôtel Métropole. Nearly 100 members and guests assembled, among whom were Mr. V. Horsley, the Sheriff, the President of the Northumberland and Durham Medical Society, and others. Professor Murray occupied the chair. An excellent dinner was provided, and a very pleasant evening spent.

The Toy Pistol again.

A youth is under treatment in the Royal Infirmary, Newcastle-upon-Tyne, owing to a pistol accident. He was amusing himself in his bedroom firing at a mark. The pistol was a breechloading one, and to open the breech it was necessary to turn the barrel at a right angle, the muzzle being directed towards the person loading it. Not infrequently the pistol misfired, and it was after such an occurrence, the cartridge being *in situ* but unexploded, that in the attempt to extract it the breech was opened. Immediately the cartridge exploded, the ball entering the lad's chest, which was bare just over the heart. On admission, nearly three weeks after the occurrence, the lad was in a very critical condition, the left chest being filled with pus. He had never spat blood, and did not suffer much inconvenience till fluid accumulated. The chest has been incised and the lad is progressing satisfactorily. How long are these dangerous weapons to be legally sold as toys?

Newcastle-upon-Tyne, Feb. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Discussion on Cardiac Therapeutics at the Medico-Chirurgical Society, Edinburgh.

AT the meeting of this society last week a discussion on Cardiac Therapeutics was inaugurated. There was a considerable attendance of members and a goodly number of senior students, whose presence made the room somewhat crowded and the atmosphere oppressive and unhygienic.

The opening of the discussion devolved upon Dr. Fraser, Professor of Materia Medica and Therapeutics and an infirmity physician. It was, of course, an admirable opportunity for a masterly statement of the present position of the subject from a purely scientific standpoint, as well as from a practical one, tested and weighed by the results of a considerable experience in hospital practice. The opener, however, devoted himself almost exclusively to strophanthus. Its pharmacological action was indicated, and its practical use was illustrated by a number of hospital cases in which he had used it with success. The insistence on the merit of one drug would have been more effective had the discussion been one on strophanthus; as an introduction to the larger subject it necessarily was less so. Dr. Fraser was followed by Dr. G. W. Balfour, who expressed his determined adherence to digitalis. The discussion was postponed for a fortnight, and Dr. Bramwell, Dr. Russell, Dr. Gibson, and others are expected to speak at the next meeting.

President's Reception at the Royal College of Physicians of Edinburgh.

Last Friday night Professor Gairdner and Mrs. Gairdner gave a reception to the Fellows of the Royal College of Physicians in the College rooms in Queen-street. The rooms are large, and as few save Fellows and the ladies who accompanied them were present they had a somewhat bare and empty look. Much, however, had been arranged for the edification and entertainment of the guests. In addition to a good supply of music there were interesting demonstrations by Professor Rutherford, Dr. Carlier, and Dr. Gustave Mann, while Professor McKendrick had sent a phonograph which provided a variety entertainment in itself.

Health of Edinburgh.

Amongst the deaths in Edinburgh last week were two from small-pox. Three fresh cases of this disease were reported. Measles have reached an epidemic level, 580 cases having been reported during the week.

Glasgow Royal Infirmary.

The recently issued annual report of this institution—interesting as being the hundredth annual publication of its kind—shows that during the year 1894 the admissions were 5527; deaths, 540; mortality, 9.7 per cent., or, deducting 122 deaths occurring within forty-eight hours of admission, 7.7 per cent.; average residence of in-door patients, thirty-five days. The cost of each fully occupied bed was £56 2s. 8d., and the average cost of each patient treated to a conclusion, £5 8s. 11d. In the out-door department 55 104 consultations were held. The total revenue of the infirmary for the year was £30,505 15s. 6d.; total expenditure, £30,143 12s. 2d.; giving a surplus on the year's work of £362 3s. 4d. The managers intend to extend the pathological department and spend on the project £8000, for which sum they appeal to all those interested in the welfare and efficiency of the infirmary. For a long time everyone has been dissatisfied with the accommodation provided for the pathological department, which has really undergone very little change since it was first organised, while the house at large has been altered and extended in every way. The managers also acknowledge a complete electrical plant, consisting of gas-engine, dynamo, and all the accessories required for surgical and medical treatment and diagnosis, together with an electric lantern microscope for teaching purposes.

Public Health in Glasgow.

The death-rate in Glasgow for the past week has risen to 32 per 1000, an increase due to the present extreme cold. There has been but one case of small-pox reported since last Wednesday (Feb. 6th), while there have been dismissed from hospital, making a net decrease of two cases, there being now but 37 in Belvidere Fever Hospital.

Glasgow: Inconveniences caused by the Frost.

The Victoria Infirmary is entirely dependent on its boilers and engines for cooking, lighting (electric, there being no gas-fittings in the building), heating, and ventilation, the latter being managed on the "propulsion" system, whereby washed and warmed air is driven through the wards. When, therefore, the engines stopped for want of water for the boilers, the feed-pipe from the water main being frozen, the infirmary was at once plunged into difficulties of a very mixed kind. These have been got over for the time being by having a steam fire-engine from the city to pump water to the infirmary from the nearest hydrants. This breakdown,

however, and the serious consequences to which it might easily have given rise, teaches the lesson that in an institution of the kind it is not good policy to trust to one source of energy for the performance of so many functions.

Feb. 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Health of Dublin: Quarterly Report.

DURING the quarter ended December last the births registered in the Dublin registration district amounted to 2314, or 26.5, and the deaths to 2047, or 23.4 per 1000. The number of deaths from zymotic diseases amounted to 250, or 26 over the number for the preceding quarter. Of these, small-pox caused 51 deaths, of whom 27 were unvaccinated, 21 had been vaccinated, 1 infant was vaccinated too late, and in 2 cases there was no statement as to vaccination. As regards the ages of the persons who died from small-pox and their relation to the protective power of vaccination, it is to be noted that all the 9 children under five years of age were unprotected by vaccination (1 having been vaccinated too late), and of 42 persons above five years of age, 19 were unvaccinated and 21 were vaccinated; all of those vaccinated except 1 (aged six) were over seven years of age, the period at which the protective power of primary vaccination is known to be weakened. Enteric fever caused 45 deaths, or 10 over the number for the preceding quarter, typhus fever only 1 death, and simple continued fever also 1 only, scarlet fever caused 11 deaths, being 33 under the average, influenza 15 deaths, and diarrhoea and dysentery 55.

Richmond Lunatic Asylum.

At a meeting of the governors last Tuesday Mr. C. Norman, resident medical superintendent, reported that there were at present in the asylum 715 male patients and 765 female patients, or a total of 1480. These numbers were respectively 210, 170, and 380 above the nominal limit of accommodation. Since the last meeting of the board five fresh cases of dysentery had occurred in the asylum and two deaths had taken place.

The Battle of the Clubs at Cork.

A meeting of the City of Cork Branch of Oddfellows was held last week. The proceedings, for obvious reasons, took place inside closed doors, and only an official communication appeared in the local press, yet the amount of information allowed to filter through is well worth recording as illustrating the frame of mind of many of the club members, and demonstrates pretty clearly the slow, but sure, crystallising process which is taking place. One of the brotherhood moved a resolution—of which he had given notice—that a member of the lodge need not contribute to the fund for the medical officer if he did not choose to do so. In other words, the proposition was that all should subscribe to the fund for relieving sick members and burying deceased ones, but that if any member did not care to engage the services of the newly appointed medical man he would be under no obligation to contribute to his salary. This proposition very nearly commended itself to a majority of those present. The resolution was finally rejected, but only by the casting vote of the chairman. That decision clearly meant that fully one-half of those in the room were anxious to be at liberty to call in any medical man they might select. What may be the action of this thoughtful half remains to be seen, but to-day large posters are exhibited announcing that a meeting is to be held on the 21st inst. to consider the dispute. As it is ostentatiously mentioned that there will be free admission I have no doubt many of the affluent members of the clubs will find no difficulty in putting in an appearance, and the medical men may be prepared for the ordinary amount of oratorical vituperation. But any thoughtful observer will ask what is the need for this meeting at all. The practitioners of the city considered the services of a medical man ought not to be offered to the clubs at a lower rate than certain specified prices. The clubs thought differently, and after searching north and south, east and west, they find some six or eight members of the medical profession ready to accept their terms. Out of this group each recalcitrant club and association has made its selection. If happy in their choice, why seek to evoke public sympathy in their favour? The local practitioners see no necessity for

rushing into the market-place. Deeds, not words, is their motto. They are quite satisfied as to the justice of their action, so they simply rest on their oars and are quiet observers of current events. Since the snow commenced to spread its white mantle over the earth one of the imported practitioners finds himself famous in the annals of one of the local newspapers. A paragraph seriously announced that the medical man was passing the College on his way to visit a patient when he was seriously assaulted with snowballs by students. The students, however, give an entirely different version. They state that they were amusing themselves and at the same time endeavouring to keep up their temperature by throwing snowballs at each other. The medical man happened to pass along, and, believing one of the snowballs was intended for him, rushed at one of the students and struck him so violently with a stick that it was broken across his back. The student turned round, and, though unarmed, went for his opponent so vigorously that the latter's practice was immediately increased to the extent of necessitating the prescribing for a case of epistaxis in propria persona. One local print is, of course, quite satisfied that the whole thing was premeditated. The local medical men knew the imported practitioner had a patient in that direction. Then they procured a fall of snow, and, knowing from their own experience that embryo medical men could not amuse themselves without being vicious, they gave the hint to the students to be ready for action at the crucial moment. Such is the farrago to which we are now accustomed and at which we can afford to smile.

The Belfast Asylum.

At the monthly meeting of the governors, held on Feb. 11th, the medical superintendent reported that the house was overcrowded, there being 645 patients in residence, and it was necessary to supply more bedsteads in the corridors for the accommodation of the patients admitted. The committee appointed to investigate the question of the lighting of the new projected asylum (Purdysturn House) found that gas would involve an expenditure of £100 less annually than electricity, and consequently they recommended its adoption. Regarding the sewage question, there was a difference of opinion amongst the governors. The subcommittee agreed with the architects in advising the adoption of the international system of sewage purification. Some members of the board strongly objected to this system of sewage on the ground that it had broken down when tried in London, and finally it was decided to ask the board of control to give special attention to, and to transmit their views on, the subject, and to say if they thought it suitable for Purdysturn Asylum or whether they can suggest any better plan.

The Ulster Hospital for Women and Children.

At the annual meeting of the friends of this charity, held on Jan. 31st, it was stated that there had been 8624 extern patients during the year—7049 children and 1575 women. There were 211 intern cases. An intern maternity ward has also been fitted up, which has been found of much value. Dr. Mitchell has been appointed a member of the staff in place of Dr. John Scott (deceased).

Mr. O'Gorman, L.R.C.S. Irel., Ballyragget, has been placed on the Commission of the Peace for the county of Kilkenny.

Mr. W. K. Parry, A.M., has been appointed Examiner in Practical Sanitary Engineering to Trinity College, Dublin.

Feb. 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Etiology of Dysentery.

M. DE SILVESTRI¹ relates the results of his recent researches into the nature of dysentery based upon bacteriological examination of the characteristic stools, which were of a lemon-yellow colour, liquid, had floating in them lumps of blood-stained mucus, and emitted a very marked faecal odour. The microscope brought to view particles of undigested food, débris of epithelial cells, red blood-corpuscles, and numerous bacteria, amongst which a diplococcus predominated largely.

¹ Société de Biologie, Feb. 2nd.

A culture yielded a number of colonies composed almost exclusively of the diplococcus referred to above. This micro-organism is round, stains with difficulty, is not coloured by Gram's method, and does not liquefy gelatine. It grows rapidly (in eight hours) in different media. A culture of the diplococcus mixed with sterilised water and injected per rectum into a dog and two cats determined diarrhoea quite recalling the characteristic features of that of dysentery, the stools containing the diplococcus. M. de Silvestri opines that there exist several varieties of dysentery due to different specific micro-parasites, but that the *origo mali* in the epidemic observed by him was the diplococcus in question.

The Temperature in Experimental Diptheria.

MM. Courmont and Doyon² have been engaged in studying the oscillations of temperature in the dog, the rabbit, and the guinea-pig inoculated with diphtheria toxins. With a small dose hypothermia lasting from five to six days appears after an interval of eighteen hours. The animal survives, but is paralysed. A larger dose determines at first a fall of 1° to 2° C., lasting about fifteen hours, when a further fall suddenly occurs, and the animal dies in one, two, or three days, with a rectal temperature of only 30° or even 25° C. A still stronger dose (50 c.c.) brings about hypothermia after a reduced incubatory period of two or three hours, and the animal quickly succumbs. Death may occur even before the onset of hypothermia. From these experiments it would appear that the diphtheria toxine is endowed with hypothermic properties and that the fall of temperature is always preceded by an incubatory period varying, according to the dose administered, from two to eighteen hours. The fall is quicker or slower according as the medium in which the animal is placed is cold or warm. That the hypothermia is not the cause of death is proved by the fact that it supervenes as rapidly in animals placed in an oven at 40° C. as in those kept in the cold and whose rectal temperature has descended before death to 25° C.

The New Premises of the Academy of Medicine.

I have on several occasions referred to the insufficient accommodation afforded by the dingy building in the Rue des Saints-Pères, which, although only a *dépendance* of the Charité Hospital, is the home of the learned body, the Paris Academy of Medicine. In the near future the Academy will be transferred to more commodious quarters in the Rue Bonaparte, near the École des Beaux-Arts. Here an unoccupied building belonging to the Assistance Publique has been allotted to the corporation, who can only be congratulated on the long-desired change.

"English as she is wrote."

Summoned to attend the child of one of my patients the other day, I found that, alarmed by baby's serious state, a French *confrère* had already been sent for and left directions which a neighbouring French druggist had translated for the benefit of the English nurse in charge. The document is too amusing to be passed over, and I therefore make no apology for transcribing it, together with the necessary explanation within parentheses supplied by myself: 1. To distend the children of other children. (To isolate the baby from her sister.) 2. Not many flower in the eat and not give him that milk prepared. (Suppress farinaceous food and also the milk as hitherto prepared.) 3. Before the col of children use éponge warm." (Apply a hot sponge to the child's throat.) 4. Every body that have occupation of children wild vbach the hands in liquor of van Swieten. (Every person coming in contact with the child to wash his hands in van Swieten's solution.) 5. All the linen deteriorated shall be wbach in solution before londres. (All soiled linen to be washed in the solution before being sent to the laundress.)

Death of Professor Regnaud.

The death is announced of M. Regnaud, Honorary Professor of the Paris Faculty of Medicine. Before he had reached the age-limit necessitating retirement he occupied for many years the chair of Pharmacology. I well remember how, at the first examination I passed at the Faculty, he propounded to me, in his own genial fashion, a question on induction, and how he exclaimed, "Votre compatriote Faraday était, à mon avis, le plus grand savant qui ait jamais existé. J'ai eu l'honneur de lui serrer la main à Lyon en 18—."

Feb. 12th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Czynski Trial.

A MOST remarkable case was brought before a jury of Munich some weeks ago. A Pole, Czynski by name, gave in several German towns hypnotic stances which were largely attended by sick people. In the course of these performances he made the acquaintance of a certain rich and noble spinster who consulted him at first unromantically for stomach affection. Later their relations became more intimate, and finally, it appears, the lady became Czynski's mistress. He, it seems, was not yet divorced from his first wife, and a marriage ceremony, which he went through with his victim by the usual help of a friend in the rôle of clergyman, was a sham. At the instance of the lady's brother Czynski was arrested on a charge of "crime against morality." The public attorney's indictment accused the prisoner of having violated the lady while in a state of hypnosis. The defendant denied the crime, and asserted that the lady loved him and had married him of her own free will. Czynski's counsel submitted that it would not be possible to deprive a person of will by hypnosis, and medical men were summoned as experts to give evidence to this end. Professor Fuchs of the University of Bonn asserted that hypnosis was unable to annihilate the freedom of will. He had seen hypnotised people in Paris and was persuaded that they had done what the operator ordered them either to oblige him or to pose as interesting. In short, he held all hypnotism to be a farce. Professor Preyer and Professor Hirt declared that they were of an entirely contrary opinion, but they also said that the Paris experiments quoted by Professor Fuchs did not prove anything, as nearly all the mediums there were drilled for hypnotic performances. The jury finally acquitted Czynski of having violated the lady while in a state of hypnosis, but condemned him to three years' imprisonment for frauds in connexion with the false marriage. Professor Preyer has given his opinion of the verdict in the *Deutsche Medicinische Wochenschrift*. He declares himself to be fortified in his view that Czynski not only hypnotised his victim but also her companion, who had acted as witness at the wedding ceremony, and even the man who impersonated the clergyman. He has come to this result after examination of their signatures to the marriage register, which, he believes, offer some very characteristic signs. He also alludes to a condition where the person is not really reduced to hypnotic somnolence, but is merely influenced by the strong will of the operator. This state, which he has sometimes seen, especially in people of a weak character, he terms "abulia." The questions involved being of great medico-legal and scientific interest, the various professors called as experts intend to collaborate in producing a pamphlet on the case.

The Number of Medical Men in Germany.

The number of German medical men increases from year to year. At the end of 1894 there were 22,287 medical men, whilst there were 21,621 in 1893, and 16,864 only in 1887. Of these, 1834 live in Berlin, 438 in Munich, 355 in Breslau, 314 in Leipzig, 236 in Hamburg, 233 in Frankfurt, and 220 in Strasburg. There are now on an average 4.5 medical men for 10,000 inhabitants, in 1887 there being only 3.6. The number of dentists equally has increased from 915 in 1893 to 1007 in 1894.

How should the Surgeon clean his Hands?

In Germany the usual method for surgeons to clean their hands is that of Fürbringer. It consists in brushing the hands and nails with soap and hot water, then dipping them in an 80 per cent. alcohol solution, and finally washing with a 2 per cent. sublimate of mercury, each part of this proceeding to last one minute. Recently Reinecke of Leipzig has asserted that a sure disinfection of the hands may be obtained by rubbing them with alcohol only and washing afterwards with pure sterilised water. The alcohol owes its power to its action in dissolving the sebaceous substance on the surface of the skin and enabling the bacteria which adhere to it to be easily washed away. Instead of brushes, which are difficult to clean and which irritate the hands, he recommends loofah sponges. Another reformer in this matter is Dr. Schleich, who rejects all brushing, and only washes the hands with a soap invented by himself, which consists of

domestic soap (one part), marble powder (three parts), and lysol (4 per cent. of the whole). This soap is said to clean less by chemical than by mechanical means, the fine marble powder penetrating into all the folds of the skin and rubbing away all dirt and detritus.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Antitoxin Treatment of Diphtheria in Russia.

THE main source of supply of the diphtheria antitoxin in St. Petersburg is the Imperial Institute of Experimental Medicine. Serum derived from German firms is also on sale in the druggists' shops in the city. The serum which the Institute supplies is partly obtained from Germany and partly prepared in the laboratories of the Institute. In the first two weeks of the present year (Old Style) the Institute sold as many as 2500 bottles of the serum, for which they received some 8500 roubles (nearly £900 at the present rate of exchange). The price of the antitoxin in St. Petersburg appears to be fairly constant, but in some provincial towns, it is worthy of note, where it is on sale at druggists' shops, the price varies enormously. For instance, in Kharkof some druggists charge 5 roubles while others charge 20 roubles for exactly the same quantity of serum. The profit in the latter case must be considerable. But little has been published yet as to the clinical results obtained in Russia by the use of the antitoxin in the treatment of diphtheria. At a meeting of the Society of Specialists in the Diseases of Children Dr. Rauchfus reported thirty completed cases occurring in the Prince of Oldenburg's Hospital for Children in St. Petersburg in which he had employed the new treatment. Of the 30 cases, 19 recovered and 11 died; this gives a death-rate of 36.6 per cent. All the cases were well-marked cases of diphtheria, and in all the presence of Löffler's bacillus was demonstrated. The average age of the nineteen children who recovered was 4.6 years; they were admitted on the third to the sixth day of the disease; separation of the membrane began two and a quarter days after the first injection and lasted for five and a half days. Most of the patients had albuminuria. Of the 11 fatal cases the majority were children of one to three years of age; in all of them the symptoms were stated to have been extremely severe, and the majority died within twenty-four hours after injection. All the cases were treated during November and December. During these months one half of the diphtheria cases admitted to the hospital were treated by the method of serum injection and the other half by the older methods of treatment. The mortality among the former was 36.6 per cent., while among the latter, who received no injections, it was 52 per cent. Erythema was a frequent result of the new treatment; it appeared equally often, whether Behring's or Roux's serum were employed. In conclusion, the writer of the paper considered his results as encouraging, though not conclusive. He mentioned that Professor Filatof had obtained much better results: he had treated 9 cases, with only 1 death.

Changes in Russian Medical Journals.

The *Chirurgicheski Věstnik*, or *Surgical Messenger*, the monthly journal edited by Dr. Veliaminof, is henceforth to be called the *Russian Archives of Surgery*, and will appear quarterly instead of monthly, as heretofore. The removal of Professor Kovalevski from Kharkof to Warsaw, in consequence of his appointment to the Rectorship of the Warsaw University, will affect two medical journals. The *Archives of Psychiatry, Neurology and Legal Psychology*, hitherto published in Kharkof, will now be published in Warsaw; and the *Journal of Medicine and Hygiene*, published by the Kharkof Medical Society, will cease to exist.

Forthcoming Medical Conferences in Russia.

A conference of practitioners in the province of Podolia has been summoned to meet this month in Kamenetz-Podolsk, the capital of the province, to discuss the cholera epidemic, from which Podolia has suffered more severely than almost any other part of Russia during the past three summers. It is proposed to hold next year in Russia a conference of syphilologists. The tenth congress of Russian naturalists and physicians will be held in Kief next year.

St. Petersburg, Feb. 9th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Condemnation of the Game of Football.

A RECENT football match between the students of two of our colleges, the most important because the most popular trial of the year, was attended with so much "slugging" that the immense audience were thoroughly disgusted with the scenes of brutality which they witnessed. Even experts in the game were compelled to protest against the inhuman acts which were encouraged by the managers on both sides. A large number of severe and crippling injuries have been recorded, and the surgeon and his assistants were as busy as a surgeon on the field of battle. The result of this contest between the teams of two favourite colleges has been a severe set-back to this hitherto popular game. In the opinion of the President of Harvard University the game of football grows worse and worse as regards foul and violent play and the number and gravity of the injuries which the players suffer. It has become perfectly clear that the game as now played is unfit for college use. The rules of the game are at present such as to cause inevitably a large number of broken bones, sprains, and wrenches even during trial or practice games played legitimately; and they also permit those who play with reckless violence or with shrewd violations of the rules to gain thereby great advantages. What is called development of the game has steadily increased its risks, until they have become unjustifiable. Naturally the public is losing faith in the sincerity of the professed desire of coaches, captains, and promoters to reform it. The players themselves have little real responsibility for the evils of the game. They are swayed by a tyrannical public opinion—partly ignorant and partly barbarous—to the formation of which graduates and undergraduates, fathers, mothers, and sisters, leaders of society, and the veriest gamblers and rowdies all contribute. The state of mind of the spectators at a hard-fought football match cannot but suggest a query as to how far these assemblies differ at heart from the throngs which enjoy the prizefight, cockfight, or bullfight, or which in other centuries delighted in the sports of the Roman arena. Several fatal accidents have happened this year to school-boys and college students on the football field, and in every strenuous game now played, whether for practice or in an inter-collegiate or other competition, there is the ever-present liability to death on the field. It is often said that by employing more men to watch the players, with authority to punish instantly infractions of the rules, foul and vicious playing could be stopped. The sufficient answer to this suggestion is that a game which needs to be so watched is not fit for genuine sportsmen.

A National Health Department.

The President has urged upon Congress in a recent message to that body the necessity of such legislation as will create a well-organised and efficient Health Department in the general Government. This is the first time that a President has recommended a national board of health in decided and emphatic language. He says: "I am entirely convinced that we ought not to be longer without a national board of health or national health officer charged with no other duties than such as pertain to the protection of our country from the invasion of pestilence and disease. This would involve the establishment by such a board or officer of proper quarantine precautions or the necessary aid and counsel to local authorities on the subject, prompt advice and assistance to local boards of health or health officers in the suppression of contagious disease, and in cases where there are no local boards or officers the immediate direction by the national board or officer of measures of suppression; constant and authentic information concerning the health of foreign countries and all parts of our own country as related to contagious diseases; and consideration of regulations to be enforced in foreign ports to prevent the introduction of contagion into our cities and the measures which should be adopted to secure their enforcement." There seems to be at this time a decided inclination to discuss measures of protection against contagious diseases in international conference with a view of adopting means of mutual assistance. The creation of such a national health establishment would greatly add to our standing in such conferences and improve our opportunities of availing ourselves of their benefits. At the last session of Congress several Bills were under discussion as to creating a health department,

but no measure was finally agreed upon. A new Bill has now been drawn with respect to which all parties unite and which will meet with no effective opposition.
Feb. 1st.

Obituary.

CHARLES MOSS, M.R.C.S. Eng., L.S.A.

MANY old King's College men will hear with regret of the death of Mr. Charles Moss on the 8th inst. from acute intestinal obstruction. He was seized with abdominal pain on the previous day, and though evidently ill he kept an appointment at Dr. Wharton Hood's house in the afternoon, but while there he fainted and was taken home in a cab. Dr. Duffin saw him the same night and again the next morning in consultation with Dr. Cayley, and it was agreed to ask Mr. Christopher Heath to see him at midday on Friday, but he died before the consultation was held. Charles Moss was a native of the Cape of Good Hope, and went to King's College older than the average student. He became a Member of the Royal College of Surgeons of England in 1862, and was for some time house surgeon at the Moorfields Ophthalmic Hospital. Here he had considerable experience in the administration of anaesthetics, so that he was prepared to take up that work for Sir William Fergusson, both at the hospital and in private, when the late Dr. Anstie gave it up about 1863. Mr. Moss for many years absolutely discarded chloroform, and invariably administered the A.C.E. mixture when not giving gas for dental operations. He was able to boast that he had never had a fatal case in his long practice, and looked upon strong ammonia inhalation as his sheet-anchor in cases of heart failure. He held the post of anaesthetist to King's College Hospital for many years, but upon the retirement of his old friend Mr. Henry Smith he resigned, and of late years had confined himself to the practices of old friends, by whom he was much appreciated, both professionally and socially. He was buried at Kensal-green on Wednesday last.

ALBERT RICHARD WAGHORN, M.D. ST. AND.,
M.R.C.S. ENG., L.S.A.,

SURGEON-MAJOR, BENGAL ARMY (RETIRED).

DR. ALBERT RICHARD WAGHORN, whose death we regret to announce as having taken place on Feb. 6th, received his medical education at King's College Hospital. He became a Member of the Royal College of Surgeons and Licentiate in Midwifery in 1854. In June of the same year he received his commission in the Indian army, and shortly after went to Calcutta in charge of troops. When the mutiny broke out he was serving as civil surgeon at Hirsar in the Punjab. The other English officials with their wives took refuge at the time of the massacre; this he refused to do, and offered the use of his camels to the women, but this offer was declined. Every European in the place was murdered with the exception of himself and a sergeant who remained with him in his bungalow. Mounting a camel he rode with this man out into the jungle, and after wandering for a night and day made his way to Delhi. Dr. Waghorn was Surgeon-Major in the Bengal army. He served at the siege, assault, and capture of Delhi in 1857, receiving a medal and clasp, and in the Bhootan campaign in 1865, for which he received a similar decoration. He was Acting Superintendent of Vaccination for the North-West Provinces in 1867-8, and subsequently Civil Surgeon of Mirzapore. During 1872-3 he was on leave in England, and became a Licentiate of the Society of Apothecaries and an M.D. St. Andrews. On his return to India he served with the 26th Native Infantry until he retired from the service in 1881. From that time until 1893 he was in practice at Redhill, when his health failing he retired from active work. Dr. Waghorn contributed to THE LANCET of Nov. 15th, 1873, an account of an Unusual Case of Urethro-vesical Calculus and quick Recovery, and an article on Stimulants in the Treatment of Pneumonia on Aug. 3rd, 1878.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—Dr. D. Hicguet of Liège, a well-known and much regretted surgeon of that city. He was chief surgeon to the *Hospice*

des Anglais and one of the founders of the Liège Medico-Chirurgical Society. During the Franco-German War he had a large number of wounded under his care at Liège, and in recognition of his services to the French he received the ribbon of the Legion of Honour. He wrote various papers on surgical subjects in French and Belgian Medical Journals and was one of the earliest members of the staff of *Le Sculptel*. He had been in practice for some forty-five years.—Dr. D. K. Rodziewski, Extraordinary Professor of Pharmacology in the University of Kharkoff.—Dr. L. Rouge, formerly editor of the *Bulletin de la Société Médicale de la Suisse Romande*.—Dr. H. C. Lombard, President of the International Congress of Hygiene and Demography held in Geneva in 1882.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the College:—

Andrews, Henry Arthur, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Ashton, Joseph, L.R.C.P. Lond., St. Mary's Hospital.
 Astbury, Thomas, L.R.C.P. Lond., Mason College and Queen's and General Hospital, Birmingham.
 Badcock, Ernest Reginald, L.R.C.P. Lond., London Hospital.
 Bagshawe, Arthur William Garrard, L.R.C.P. Lond., Cambridge University and St. George's Hospital.
 Barber, Maurice Charles, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
 Barford, Percy Crompe, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Barker, Gordon Campbell, L.R.C.P. Lond., St. George's and King's College Hospital.
 Barrett, James Wilkie Collingwood, L.R.C.P. Lond., Mason College and Queen's and General Hospital, Birmingham.
 Best, Frederick Henry de Graves, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Bloomfield, Herbert Wadmore Gissing, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Bousfield, Arthur, L.R.C.P. Lond., King's College Hospital.
 Brakenridge, Francis John, L.R.C.P. Lond., St. Thomas's Hospital.
 Brewerton, Elmore Wright, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Bromet, Edward, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Brooks, William Patrick, L.R.C.P. Lond., Charing-cross Hospital.
 Bryant, Charles Henry, L.R.C.P. Lond., Durham University and Guy's Hospital.
 Burrell, Lionel Cottingham, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Chandler, George, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Chapman, Walter, L.R.C.P. Lond., Mason College and Queen's and General Hospital, Birmingham.
 Charsley, Gilbert William, L.R.C.P. Lond., Oxford University, Mason College and Queen's and General Hospital, Birmingham.
 Christmas, Robert William Samuel, L.R.C.P. Lond., Charing-cross Hospital.
 Clay, David Lloyd, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Clay, Francis Edmund, L.R.C.P. Lond., Westminster Hospital.
 Cole, George, L.R.C.P. Lond., King's College Hospital.
 Collier, Henry William, L.R.C.P. Lond., Guy's Hospital.
 Collings, Dudley Willis, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Connell, Walter Thomas, L.R.C.P. Lond., Kingston General Hospital and Queen's University, Kingston, Canada.
 Constable, John Cecil, L.R.C.P. Lond., Guy's Hospital.
 Cotter, George Edmund Wentworth, L.R.C.P. Lond., Cambridge University and St. Mary's Hospital.
 Crossley, Richard, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Cummings, Arthur Pollard, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
 Cunliffe, Thomas Varley, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Currey, Edmund Francis Neville, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Daniel, Edgar George Clement, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Davidson, Guilford, L.R.C.P. Lond., St. Thomas's Hospital.
 Davis, Henry John, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Dawes, Christopher Dering, L.R.C.P. Lond., St. George's Hospital.
 Dillon, Rupert Wentworth, L.R.C.P. Lond., St. Thomas's Hospital.
 Dockray, John Smalley, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Duke, Robert Everet, L.R.C.P. Lond., University College Hospital.
 Eder, Montague David, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Ensor, Cecil Arthur, L.R.C.P. Lond., Guy's Hospital.
 Recombe, William, L.R.C.P. Lond., Charing-cross Hospital.
 Evans, Edgar Griffith, L.R.C.P. Lond., Guy's Hospital.
 Every-Clayton, Leopold Ernest Valentine, L.R.C.P. Lond., Guy's Hospital.
 Finch, Herbert Jonathan, L.R.C.P. Lond., Westminster Hospital.
 Flint, Thomas Buxton, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.

Forrester, William, L.R.C.P. Lond., Bengal Medical College, Calcutta, and St. Thomas's Hospital.
 Fry, Augustine Craddock, L.R.C.P. Lond., Guy's Hospital.
 Gibbes, Lewis Nicholas, L.R.C.P. Lond., St. George's Hospital.
 Giles, Leonard Thomason, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Greenway, Charles Melville, L.R.C.P. Lond., Guy's Hospital.
 Greenwood, Augustus Charles, L.R.C.P. Lond., Middlesex Hospital.
 Hampton, Thomas, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Hancock, George Charles, L.R.C.P. Lond., Westminster Hospital.
 Handley, William Sampson, L.R.C.P. Lond., Guy's Hospital.
 Harding, Lionel Nicholson, L.R.C.P. Lond., Cambridge University and St. Mary's Hospital.
 Hayes, Reginald Hewlett, L.R.C.P. Lond., Trinity College, Dublin, and Guy's Hospital.
 Hedges, Charles Edward, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Henderson, Robert, L.R.C.P. Lond., Guy's Hospital.
 Hinds, Herbert Austen, L.R.C.P. Lond., Guy's Hospital.
 Hodge, Albert, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Home, Alfred Lucette, L.R.C.P. Lond., St. Thomas's Hospital.
 Hooper, Arthur Winsmore, L.R.C.P. Lond., St. Thomas's Hospital.
 Horner, William Ernest Leatham, L.R.C.P. Lond., University College Hospital.
 Horseman, Frederick, L.R.C.P. Lond., Yorkshire College and General Hospital, Leeds.
 Horton, James Henry, L.R.C.P. Lond., Guy's Hospital.
 Horwitch, David, L.R.C.P. Lond., Mason College and Queen's and General Hospital, Birmingham.
 Hosford, John Stroud, L.R.C.P. Lond., University College Hospital.
 Hughes, Burroughes Maurice, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Hughes, Robert, L.R.C.P. Lond., St. Thomas's Hospital.
 Hughes, Robert Thomas, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Hugo, James Henry, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Jackson, Francis Seymour, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Jacob, Frank Harwood, L.R.C.P. Lond., King's College Hospital.
 James, Sydney Price, L.R.C.P. Lond., St. Mary's Hospital.
 Jeffery, Charles Chinnio, L.R.C.P. Lond., Charing-cross Hospital.
 Jones, Richard Llewelyn, L.R.C.P. Lond., University College Hospital.
 Kearney, Charles James, L.R.C.P. Lond., Guy's Hospital.
 Kettlewell, George Douglas, L.R.C.P. Lond., London Hospital.
 Knight, Henry, L.R.C.P. Lond., St. Thomas's Hospital.
 Leon, George Alexander, L.R.C.P. Lond., London Hospital.
 Levy, Oscar Ludwig, L.R.C.P. Lond., Munich, Berlin and Freiburg Universities and Westminster Hospital.
 Linnon, Frederick, L.R.C.P. Lond., Charing-cross and St. Thomas's Hospital.
 Mackintosh, John Stewart, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Mansergh, William, L.R.C.P. Lond., Owens College, and Royal Infirmary, Manchester.
 Mathew, Charles, L.R.C.P. Lond., St. Mary's Hospital.
 Mayne, William Sidney, L.R.C.P. Lond., University College Hospital.
 Messiter, Frederic Gerald, L.R.C.P. Lond., Mason College, and Queen's and General Hospital, Birmingham.
 Milward, Frederic Victor, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Morison, Henry Baumerman, L.R.C.P. Lond., Durham University and Middlesex Hospital.
 Morrison, Alexander, L.R.C.P. Lond., University College Hospital.
 Morrison, David, L.R.C.P. Lond., University College Hospital.
 Newington, Charles Willmott Henderson, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Norris, Frank Baker, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Oliver, Richard Sobey, L.R.C.P. Lond., King's College Hospital.
 O'Malley, Edward Dominic Joseph, L.R.C.P. Lond., Middlesex Hospital.
 Osborn, Edward Collet, L.R.C.P. Lond., Westminster Hospital.
 Parkinson, Walter George, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
 Pern, Horace, L.R.C.P. Lond., Guy's Hospital.
 Phillips, John, L.R.C.P. Lond., University College Hospital.
 Porter, Robert Ibbetson, L.R.C.P. Lond., Oxford University and St. Bartholomew's Hospital.
 Power, Herbert Robert, L.R.C.P. Lond., St. Mary's Hospital.
 Quait, Alexander Wortley, L.R.C.P. Lond., St. Thomas's Hospital.
 Reeves, Albert, L.R.C.P. Lond., Guy's Hospital.
 Rigby, Hugh Mallinson, L.R.C.P. Lond., London Hospital.
 Roberts, Cecil David Dale, L.R.C.P. Lond., Mason College and Queen's and General Hospital.
 Robertson, Frederick William, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Robinson, Charles Henry James, L.R.C.P. Lond., Middlesex Hospital.
 Robson, Thomas Stretton, L.R.C.P. Lond., Guy's Hospital.
 Rogers, Frederick Edward, L.R.C.P. Lond., London Hospital.
 Rost, Ernest Reinhold, L.R.C.P. Lond., St. Mary's Hospital.
 Rykert, Arthur Frederick, L.R.C.P. Lond., Toronto General Hospital and University, Toronto, Canada.
 Salter, Alfred, L.R.C.P. Lond., Guy's Hospital.
 Schnöller, Anton, L.R.C.P. Lond., Zurich, Lausanne, Berne and London Hospital.
 Sharpin, Walter Archdale, L.R.C.P. Lond., St. George's Hospital.
 Shephard, Alfred Edward, L.R.C.P. Lond., Middlesex Hospital.
 Smith, Graham Udale, L.R.C.P. Lond., King's College Hospital.
 Snoad, Philip Ephraim, L.R.C.P. Lond., St. George's Hospital.
 Stenhouse, James Wilson, L.R.C.P. Lond., Edinburgh University.
 Stokes, Frank William, L.R.C.P. Lond., University College Hospital and Durham University.

Storrs, Eric Glendow, L.R.C.P. Lond., King's College Hospital and Yorkshire College and General Infirmary, Leeds.
 Sullivan, Daniel Vincent, L.R.C.P. Lond., Queen's University and Kingston General Hospital, Kingston, Canada, and University College Hospital.
 Taylor, Herbert Stockley, L.R.C.P. Lond., University College Hospital.
 Thomas, Thomas Morrell, L.R.C.P. Lond., Guy's Hospital.
 Tinley, William Edwin Falkingbridge, L.R.C.P. Lond., St. Thomas's Hospital.
 Tregenza, William, L.R.C.P. Lond., Firth College, Sheffield, and University College Hospital.
 Waite, Joseph Edward, L.R.C.P. Lond., University College Hospital.
 Watts, Brian, L.R.C.P. Lond., Firth College, Sheffield, and London Hospital.
 Webb, Arthur Lisle Ambrose, L.R.C.P. Lond., University College Hospital.
 Weeks, Courtney Charles, L.R.C.P. Lond., University College Hospital.
 Welch, Edmund, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
 Wells, Thomas Henry, L.R.C.P. Lond., Middlesex Hospital.
 White, Arthur Thomas, L.R.C.P. Lond., Westminster Hospital.
 Williams, Richard Bridgman, L.R.C.P. Lond., St. Thomas's Hospital.
 Zumbado, Federico, L.R.C.P. Lond., Durham University and Guy's Hospital.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen having passed the necessary examinations have been admitted by the two Royal Colleges Diplomates in Public Health:—

Ferrand, Edward (Surgeon-Major, Madras Army), M.R.C.S. Eng. and L.R.C.P. Edin., St. Bartholomew's Hospital.
 Gill, Joseph William, L.R.C.P. Lond. and M.R.C.S. Eng., Middlesex Hospital.
 Helby, Ernest Hasler, L.R.C.P. Lond. and M.R.C.S. Eng., King's College Hospital.
 Jones, George, M.B. and B.Ch. Oxon., L.R.C.P. Lond. and M.R.C.S. Eng., London Hospital.
 Jones, Rowland Francis Hugh, L.R.C.P. Lond. and M.R.C.S. Eng., St. Bartholomew's Hospital.
 Meadows, Robert Thornton, M.D. and C.M. Edin., Edinburgh University.
 Moore, Samson George, M.B. and Ch.B. Vict., University College and Royal Infirmary, Liverpool.
 Newton, Henry William, L.R.C.P. Lond. and M.R.C.S. Eng., Middlesex and King's College Hospitals.
 Paine, Alexander, M.B. and B.S. Lond., St. Mary's Hospital.
 Paine, Charles, M.B. Lond., St. Mary's Hospital.
 Russell, William, M.B. and C.M. Abert., Aberdeen University.
 Simmons, Harold, M.B. and B.S. Durh., L.R.C.P. Lond., and M.R.C.S. Eng., Bristol Medical School and Middlesex Hospital.
 Wilkes, George Arthur, L.R.C.P. Lond. and M.R.C.S. Eng., Mason College, Birmingham, and Yorkshire College and General Infirmary, Leeds.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Burckhardt, Extraordinary Professor of Hygiene, has been promoted to the rank of Ordinary Professor.—*Budapest:* The duties of the chair vacated by the death of Dr. Scheuthauer are to be divided, Dr. A. Genersich of Clausenburg having been appointed Professor of Pathological Anatomy and Dr. O. Pertik Professor of Pathological Histology; Drs. Szili, Goldzicher, St. Csapodi, and Feuer, Lecturers on Ophthalmology, have all been appointed Extraordinary Professors.—*Göttingen:* Dr. Nicolaier, *privat-docent* in Medicine, has been granted the title of Professor.—*Jena:* Dr. Gumprecht has been recognised as *privat-docent* in Medicine.—*Lyons:* The Professorship of Hygiene and Forensic Medicine has been officially declared vacant.—*Padua:* Dr. T. Ferrari has been recognised as *privat-docent* in Midwifery and Gynaecology, and Dr. G. Dalle Ore as *privat-docent* in Operative Medicine.

THE WORTHING WATER-SUPPLY.—The new well at Broadwater, near Worthing, which is being constructed by the corporation, has again reached chalk, in which the workmen are excavating at a depth of 106 feet from the surface; 102 feet have been encased in cylinders, and the daily yield of water is put at three-quarters of a million gallons. This is being lifted by powerful pumps and discharged in a disused pit between the well and the town of Worthing. Mr. Monsergh reports that the progress is equal to his expectations, and that the supply of water is gradually increasing. The Local Government Board stipulates for a daily yield of 1,000,000 gallons before sanction will be granted to the loan which the corporation seeks to raise to cover the cost. This has to be obtained before the Corporation Stock can be issued, and the finances of the borough will be therefore somewhat crippled until the necessary yield is ascertained and maintained for a fortnight. The present temporary works at the foot of the South Downs are meanwhile being worked at considerable expense, although a very great waste of water has been remedied.

We learn that there is an opening in Cape Colony for a thoroughly qualified medical officer of health. The salary is £1000 a year. Applications (supported by testimonials and stating the candidate's age, date when he would be prepared to enter upon his duties, &c.) will be received by the Agent-General, 112, Victoria-street, S.W., and by the Under Colonial Secretary at Capetown, up to noon on March 15th next.

On Wednesday, Feb. 13th, before Baron Pollock and a special jury, a trial took place of great interest to medical men. Mr. Aaron Langley, a surgeon, was sued by a police constable and his wife for damages in that the defendant had, as it was alleged, seriously injured the female plaintiff by the premature use of instruments during her confinement. The jury stopped the case before the conclusion of the defendant's evidence, returning a verdict in his favour, with costs. We congratulate Mr. Langley upon such a successful termination to a very annoying position.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 31st, the President, Mr. Makeig Jones, being in the chair. A discussion on the Treatment of Diphtheria by Antitoxin was opened by Dr. Caley and Dr. Addison. Dr. Gwynne gave particulars of a severe case of diphtheria which he treated successfully with antitoxin supplied by the British Institute of Preventive Medicine. The President, Mr. Garrard, Dr. Burgess, Mr. Pye-Smith, Mr. Atkin, Dr. Martin, Dr. Samson Mathews, Mr. Lockwood, Dr. Stedman, Dr. Dyson, and Dr. Rhodes joined in the discussion.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Wednesday, Feb. 6th, 1895, Mr. F. A. Southam, M.B., F.R.C.S., being in the chair. The President delivered an address on "Recent Advances in Urinary Surgery," contrasting the surgery of the present day with that of the past, and reviewing the various operative measures which have recently been introduced in the treatment of disease of the bladder, urethra, and prostate. Dr. Mules related the history of a case of operation for radical cure of hernia where, in spite of the usual antiseptic precautions, acute œdema commenced forty-eight hours after the operation, followed by sphacelus of the larger part of the scrotum, but on the side opposite to the operation. Dr. Dreschfeld, who had taken an interest in the case, showed Koch's œdema bacilli. Free incisions over the scrotum and penis, with generous diet, brought the patient from an apparently hopeless condition to satisfactory convalescence. Dr. Mules also explained a new operation for ptosis. Mr. Walter Whitehead showed a patient after excision of the scapula, and also mentioned particulars of a singular pistol accident. Dr. Wilkinson described a case illustrating difficulties in the diagnosis of abdominal tumour.

FAREWELL DINNER TO MR. WORDSWORTH POOLE, M.B., B.C. CANTAB.—A farewell dinner was given to Dr. Wordsworth Poole in the hall of the College of Guy's Hospital on Feb. 1st, the eve of his departure for Zomba to take up the duties of Government medical officer to the British Central African Administration in the Shire Highlands, south of Lake Nyassa. Mr. R. Clement Lucas, the surgeon under whom he had formerly dressed, took the chair, and was supported by a large number of Dr. Poole's friends and fellow students. In proposing the toast of the evening the Chairman said they had met together to bid farewell and wish God-speed to a former student who was about to proceed to Central Africa, where he would be exposed to risks of climate, dangers, and hardships which in this centre of civilisation it was difficult to understand or fully appreciate. The law of the land to which he was going would be little more than the law of the individual; and he wished to assure him that in any hardships or dangers to which he might be exposed he would have the support and sympathy of his fellow students and of his profession. Dr. Jameson had shown that medical men might be illustrious administrators as well as distinguished physicians. Whatever might be Dr. Poole's future they trusted that his departure would be but the commencement of a long, a prosperous, and a distinguished career. Dr. Wordsworth Poole, in reply, said that he should always look back with pleasure to the kindness and sympathy shown to him on the eve of his departure by his fellow students. A vote of thanks to the chairman for presiding was proposed by Mr. Fagge, and briefly responded to by Mr. Lucas.

WIGAN MEDICAL SOCIETY.—The annual meeting of the above society was held on Feb. 7th, and the following gentlemen were elected office-bearers for the ensuing year:—President: Wm. Mitchell Roorcroft, M.R.C.S. Eng., &c. Committee: Wm. M. Roorcroft, G. H. Monks, jun., C. M. Brady, R. H. Cowan, M. Benson, J. P. Molyneux, and W. C. Barnish. Treasurer: G. H. Monks, jun. Secretary: Wm. Berry, F.R.C.S. Irel. The annual dinner was afterwards held, and a good muster of members and visitors were present.

THE MEDICAL REGISTERS FOR 1895.—In answer to more than one inquiry of which both the Registrar and ourselves have been the recipients, we beg to announce that the three registers of the General Medical Council for 1895 will very shortly be published by Messrs. Spottiswoode and Co. The registers are issued as soon as they can be obtained from the printers; they have been carefully revised up to date; and the usual preliminary data have been presented in tables with such improvements as constant attention may suggest.

PENDLETON PROVIDENT DISPENSARY.—The idea of a provident dispensary is no doubt an excellent one, but it requires no little tact on the part of the various members who work it to avoid friction. From Manchester we learn that the whole of the medical staff attached to the Pendleton Provident Dispensary have sent in their resignations. The cause seems to be that some affiliated dispensaries, feeling the pinch of poverty owing to the depression in trade, sent out circulars appealing to people outside to join the dispensary. This the medical staff regarded as advertising, and very properly sent in their resignations. It is fair to say that the Pendleton committee at the annual meeting repudiated the action of the affiliated societies.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—The annual dinner of this society was held at the Holborn Restaurant on Thursday, Feb. 7th. Dr. James Grey Glover, President of the society, was in the chair, and there was a large attendance of members and guests. Mr. Charters J. Symonds, President of the Hunterian Society, answered to the toast of the "Sister Medical Societies," proposed by Dr. R. W. Burnet; and Dr. G. Sims Woodhead caused much amusement by his description of the advantages and disadvantages of not being a "practical doctor" in acknowledging the toast of "The Guests," proposed by Mr. William Dingley. Mr. Frank Godfrey proposed the chairman's health, and a very pleasant and successful meeting of the society was brought to an end. The musical programme, of excellent quality, was provided by the members and their friends under the guidance of Drs. Malcolm and Remfry.

The next general meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at the County and City Asylum, Powick, near Worcester, on Thursday, Feb. 21st, 1895, under the presidency of Mr. Conolly Norman, F.R.C.P.I. Dr. Cooke will read a paper entitled "A Review of the last Twenty Years at the Worcester County and City Lunatic Asylum, with some conclusions derived therefrom"; Dr. Bond will read a paper on "Atrophy and Sclerosis of the Cerebellum"; Dr. McClaughry will read a paper entitled "Influenza as a factor in the increase of Insanity in Ireland." The next examination for the medical certificate will be held in July. Those who intend to compete for the bronze medal and prize must send in their essays to the president, Mr. Conolly Norman, Richmond Asylum, Dublin, on or before May 30th. Particulars on both subjects can be obtained of the registrar, Dr. Spence, Burntwood Asylum, Lichfield.

BURROUGHS MEMORIAL.—A meeting of the personal friends of the late Mr. S. M. Burroughs was held on Tuesday, the 12th inst., at the Cannon-street Hotel, with M. Cartelghe, the President of the Pharmaceutical Society, in the chair, to discuss what steps should be taken to perpetuate the memory of Mr. Burroughs, whose many good qualities and kind heart made him universally liked and esteemed. It was proposed that the memorial should take the form of a pharmaceutical Burroughs Scholarship, or that a Burroughs Benevolent Fund should be placed for administration in the hands of the council of the Pharmaceutical Society. By others it was preferred that the memorial should take more the form of a general charity. Subscriptions of over £350 were received up to the close of the meeting. It was resolved that a general committee be formed to further the objects of the meeting and that the executive committee consist of Mr. Michael Cartelghe, chairman; Mr. John Moss,

treasurer; Mr. H. Helbing, hon. sec.; and Messrs. Radford, Wootton, and Frank Smith. Subscriptions may be sent to Mr. John Moss, 39, Tressillian-road, St. John's, London, S.E. (Cheques to be crossed "London and County Bank.")

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Marriage with a Deceased Wife's Sister.

MR. WALTER McLAREN has given notice that on the second reading of the Bill to legalise marriage with a deceased wife's sister he will move the following amendment—viz.: "That this House is unwilling to pass a Bill which, while altering the law with respect to marriages, creates for the first time an inequality between the position of the husband and the wife and grants a privilege to the husband by enabling him to marry his deceased wife's sister which it does not give to the wife, as it does not enable her to marry her deceased husband's brother."

The Vaccination Acts.

A number of practical points in connexion with the administration of these Acts have been put before members of the Ministry by Mr. Hopwood, who appears to keep a very watchful eye upon magisterial proceedings throughout the country.

The Consolidation of the Poor-laws.

In consequence of the intimation by the Government that they do not intend during the present session to introduce a Bill for the consolidation of the Poor-laws, Mr. George Howell has given notice that on an early day he will call attention to the matter and move: "That, in the opinion of this House, it is expedient to consolidate the whole of the 135 indexed enactments relating to the relief of the poor, and also, in the same measure, the whole of the Poor-law orders of the Local Government Board, so that boards of guardians, all rating authorities, and others interested in the administration of the laws relating to the relief of the poor shall be able to comprehend what enactments and orders are in force, to understand what powers are conferred upon the guardians, and be able to apply such statutory enactments and orders in such manner as will best accord with the spirit of the age in which we live and the altered circumstances of the times as regards in-door relief and out-door relief, temporary medical assistance, the casual poor, and temporary relief works for the unemployed."

The Registration of Plumbers.

A Bill for the national registration of plumbers has again been introduced into Parliament. Its promoters, in a memorandum, state that the chief object of the measure is to afford additional safeguards to the public health by enabling persons employing plumbers to select, when they desire to do so, persons who have given evidence of their qualification for plumber's work. There has been for several years a system of registration established in the chief centres of Great Britain and Ireland, and by the Bill it is proposed to place this system upon a broader and more permanent basis. The arrangements as to the examinations for registration will be placed under the jurisdiction of a general council representing the master and operative plumbers, the Plumbers' Company, and the chief educational and sanitary bodies of the United Kingdom, with branch councils in Scotland, Ireland, and Wales. It is proposed also to give the council power to promote technical education among plumbers and to exercise discipline among those whose names are enrolled upon the register. The Bill does not contemplate any monopoly, and it does not interfere in any way with the rights of non-registered plumbers. It prohibits, however, such men from representing themselves to be registered plumbers.

Working Men's Dwellings.

A Bill has been brought in by Mr. Wrightson to give facilities for the acquisition by working men of their own dwellings. It proposes to give power to local authorities to advance money if they are satisfied that the workman actually resides or *bona fide* intends to reside in the dwelling house in respect of which the advance is applied for, that the title to the house is good, the sale is made in good faith and the price is reasonable, and that the house is in a sanitary and tenable condition. Restriction is put upon the amount of the advance and conditions are laid down as to the charge to be made to the workman, and certain borrowing powers are given to the local authorities for the purposes of the Act.

The University of London.

The Government have signified their intention of shortly introducing a Bill in the House of Lords with reference to the University of London.

Beer Adulteration.

The Bill for better securing the purity of beer provides that every person who sells or exposes for sale, by wholesale or retail, any beer brewed from or containing any ingredients other than hops or malt from barley shall keep conspicuously posted in the premises a legible notice stating what are the other ingredients. Penalties ranging from £5 to £20 are provided, and "beer" is taken to mean beer, ale, or porter.

HOUSE OF COMMONS.

THURSDAY, FEBRUARY 14TH.

Mr. Channing asked the Secretary of State for the Home Department whether his attention had been called to a sentence passed by Mr. Denman at the South-Western Police-court in September last, on F. D. Summers, of seven days' imprisonment with hard labour for non-compliance with a vaccination order; whether he is aware that F. D. Summers was, contrary to law, subjected to the hard labour regulations while in prison; and whether he will direct compensation to be made to him for this illegal punishment.—Mr. Asquith: I have communicated with the magistrate and with the Prison Commissioners, and I am informed that Summers was neither sentenced to hard labour nor subjected to hard labour. Therefore, no question arises.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALLEN, JAMES, L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Bollington Urban Sanitary District.

ANNINGTON BUSHELL, M.D. Cantab., M.R.C.S., has been reappointed Medical Officer for the Chesterton Urban and Rural Sanitary Districts.

ARROLL, CHAS., M.D., C.M. Glasg., L.R.C.S. Edin., has been reappointed Medical Officer of Health for Sheregreen.

BARBER, G. F. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Workhouse of the parish of Birmingham.

BOLT, HENRY, L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Brentford Urban Sanitary District.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

MEDICAL CERTIFICATES AND MEDICAL TITLES.

THE *Blackburn Times* editorially notices and discusses an opinion of Dr. Martin that medical men in giving certificates for use in courts of law should attach their titles to their signatures. We quite agree with Dr. Martin. Such attachment is becoming in a medical document. It does not of itself, and apart from registration, give validity to the certificate; but it is seemly and it is an additional means of identifying the certifier—whose competence should not be judged by mere common knowledge, but by his appearance in the Medical Register.

Constant Reader.—The coroner has perfect discretion in the matter, but cases quoted not infrequently in our columns show that he is not always discreet.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Could you or some of your numerous readers kindly give me any information as to the best form of an inexpensive conveyance for removing infected bedding &c. through the streets to and from the disinfecting chamber?

I am, Sirs, yours faithfully,

J. H. JENKINS.

MEDICAL RESPONSIBILITY AND BABY FARMING, &c.

Honor.—Medical relations with such a house as our correspondent describes are not necessarily prohibited, but they need to be strongly conditional. An accoucheur either in such a house or a lying-in hospital is not called on to act as a detective, but he is not to shut his eyes or give any countenance to questionable ways of dealing with children born under discreditable circumstances. He can, if he rightly uses his office, be their best friend. He should absolutely refuse to attend if children are kept without due compliance with the Act of Parliament which requires their registration. If they die without evidence of their care and medical attendance he must absolutely decline to certify. We gather that the landlady in this case is a respectable person and has every wish to comply with the law; where this is obviously not the case the medical man should decline all medical attendance beyond what humanity dictates.

Dr. Russell Steele.—We are informed that at both places the bread can be obtained by arrangement.

"THE EXHIBITION OF HYPNOTISED SUBJECTS."

To the Editors of THE LANCET.

SIRS,—Having had occasion on Friday, the 1st inst., to see Mr. Ritchie, the chairman of the board of directors of the Royal Aquarium, on a private matter, not in any way connected with the Aquarium, I went there for that purpose. I was then informed for the first time of the proposed trance. I have already, in your issue of Saturday, explained how it was that I took any prominent part in the first *séance*. Having on many previous occasions attended interesting demonstrations at the Aquarium by invitation, where I have seen numbers of medical men also present, I did not think the matter unusual. As to the second trance. I got so deeply interested in the first that I decided to watch this, purely from a scientific point of view, to see whether a six days' trance could be possible. I must confess that I was very doubtful of the fact notwithstanding I had been informed of similar cases. I also considered that if such could be proved it opened out a dangerous vista to science, inasmuch as criminal and other acts might be committed under similar circumstances, whereas it also proved that in persons susceptible of hypnotic influence it might be used to perform severe operations, and to prolong sleep in cases of mental disease requiring brain rest. I desired to be convinced on this matter, and never having had any opportunities of seeing or knowing where in England such investigations could be made I decided to grasp this occasion, and purely in the interests of science. I also decided that if such were proved to be the case some law should be passed on the subject deciding when it may or may not be used and by whom. Immediately I saw that my name was appearing in the newspapers I wrote and requested Mr. Ritchie to stop this, as it was against my wish to appear in any official or public capacity in the matter. This was, as you may have observed, immediately done. I was not directly or indirectly a party to the proceedings, and my services throughout were given voluntarily, with the sole object of testing the possibility of such a proceeding. I was informed by one who attended at the resuscitation, which took place on Saturday night, but at which I was not present, that Mr. Ritchie stated that 150 medical men had examined the case, and that many had left their cards and signed a paper as to their opinion on it, thus showing the interest taken by the profession. I might state that on being asked whether there was any danger to life whilst in a hypnotic trance I replied, so far as I knew, there were no recorded instances. I had never heard of the phthisical case until my attention was drawn to it, not being a student in hypnotism or versed in the literature of the subject, but one anxious to learn. I trust that you will give this letter the same prominence as the paragraph in Saturday's issue.

I am, Sirs, your obedient servant,
Devonshire-street, W., Feb. 11th, 1895. FORBES WINSTON.

P.S.—The man remained in a perfect state of insensibility from 3.30 p.m., Monday, the 4th, until 10.30 p.m., Saturday, the 9th inst., in spite of everything that was done to rouse him.

A TAX ON ERRAND-BOYS.

To the Editors of THE LANCET.

SIRS,—The Inland Revenue authorities want me to pay the "male servant" tax on my errand boy, whose duties are to clean knives and boots, run on errands, and take out the medicines. I shall be glad if you or some of your readers can tell me if I am liable for this tax. I may add that my father, who practised for forty years, kept a similar servant and was never asked to pay the tax. I enclose my card.

I am, Sirs, yours faithfully,
Feb. 11th, 1895. VERULAM.

A POINT OF ETHICS.

To the Editors of THE LANCET.

SIRS,—I should be thankful if you would kindly enlighten me on a question of medical ethics. In a case of a Government employé being laid up ill at home is it proper that the medical officer attached to the department should visit him, remove dressings, and make suggestions as to diagnosis and treatment, without giving his local medical attendant a chance of being present at the interview?

I am, Sirs, yours faithfully,
Feb. 13th, 1895. B. C. L.

. There can be but one answer—certainly not.—ED. L.

GRAPHOLOGY.

HANDWRITING as a diagnostic sign in obscure cases of cerebral or mental disease has lately been invested with much importance by the Italian school of anthropology, the head of which, Dr. Cesare Lombroso, the eminent Turin professor, has just issued a little volume on the subject. It is entitled "Grafologia," and is published by Ulrico Hoepli of Milan. A history of graphology, going into the handwriting of "individui normali," and showing how it illustrates individual character, precedes an elaborate examination of the handwriting of "individui anormali," in which the distinctive features of the cursive style assumed by epileptics, lunatics, and "hypnotics" is described with great minuteness, aided by the copious reproduction of facsimiles. This is much the most interesting portion of the treatise, and Dr. Lombroso's immense experience as a medico-psychological expert in criminal trials is displayed to special advantage. The "range of variation" within which the same individual, healthy as well as insane, will modify his handwriting according to his cerebral-mental condition is one of the many interesting inductions arrived at by Dr. Lombroso.

W. M. C.—The fair arrangement, it seems to us, would be to value the drugs at both times and pay half on the sum so obtained.

Mr. Thomas Lafan.—We regret to be unable to be of any practical assistance to our correspondent.

HOMES FOR CHILDREN OF DEFICIENT INTELLECT.

To the Editors of THE LANCET.

SIRS,—In reply to the query by "J. P. S." in your last issue, allow me to state that accommodation for such a case as he mentioned (presumably mentally suitable for Darent) might be obtained at moderate rates at any of the charitable institutions for imbecile children. At Earlswood (secretary, Mr. Downing, 35, King William-street, E.C.) patients are received as "put-payment" cases (specially voted for at the elections) at 15 guineas or more annually, and on full payment at 60 guineas and upwards according to requirements. At the Eastern Counties Asylum, Colchester (secretary, Mr. Turner) payment cases are taken at £50 per annum, but reduction is made to £40 if the friends cannot afford more. At the Royal Albert Asylum, Lancaster (secretary, Mr. Diggins), the full payment is 60 guineas, and the reduced (available only for residents in the northern counties) 25 guineas per annum. Payment cases are also taken at the Western Counties Idiot Asylum, Starcross, and the Midland Counties Asylum, Knowle, near Birmingham. There are a few private educational establishments also for mentally feeble children, of which I should be glad to give your correspondent information if he would write to me.—I am, Sirs, yours truly,

G. E. SHUTTLEWORTH, M.D.
Auraster House, Richmond Hill, Feb. 11th, 1895.

ADVERTISEMENT BY NEWSPAPER CARD—CAPE COLONY.

SUCH a mode of announcing the commencement of practice is not approved at home, and would be better avoided in the colonies.

C. H. W. P.—We can understand that the Local Government Board in practice would have the same difficulty as we should in theory, or more, if it set itself to lay down hard-and-fast definitions and regulations to apply to all cases alike; and we fear that we shall be unable to make the perfectly clear and authoritative statement that is desired for that reason. A systematic inspection may in some cases involve a house-to-house inspection. Undoubtedly the Local Government Board has purposely left points in its instructions to the intelligent interpretation of the individual health officer according to the actual circumstances, which he alone knows.

Enquirer.—There is no Society of United Medical Botanists in Great Britain whose diplomas are of any legal value or confer any right of practice. The advertisements are enough to stamp their authors with quackery.

FAIR COMPETITION.

To the Editors of THE LANCET.

SIRS,—Will you kindly answer the following queries in the next issue of THE LANCET? There is a forge in this town for which a medical officer is appointed every three years. A has held the appointment for several terms. The committee decided this year to have a ballot. A letter was sent to several medical men, asking if they would allow their names to be submitted as candidates. Would B, having been one of the medical men asked, have acted against any rules of medical ethics or in any way ungentlemanly in allowing his name to be placed on the list for election? A was also asked again to be one of the number. I am, Sirs, yours faithfully,

Feb. 11th, 1895. NEMO.

. If the committee has decided openly and formally to throw the appointment open there can be no reason, legal or moral, why other medical men than A should not compete for it. A could not properly feel aggrieved at candidates competing with him for the post unless he was given to understand, when originally appointed, that the post was a permanent one. We presume, as our correspondent makes no allusion to this point, that A is not being now made to undergo re-election having formerly been promised that he should not be so troubled.—ED. L.

THE DANGER OF QUACK MEDICINES.

THE *Bradford Observer* recently reported an inquest on Mr. Charles Vickermann of Huddersfield, who died at the age of seventy-three years. He was taking a patent medicine. He wrote to the vendors in London about his complaint, and they urged a continuance of the medicine. He became suddenly worse, and died before assistance could be procured. The deputy-coroner said this sort of thing should be exposed and people shown the great danger of taking medicines prescribed by persons they had never seen. The risk is too obvious. But to whom are we to look to act in the name of the public? The coroners as a body should make a representation of these cases to the Home Secretary.

A. B. M.—The Matriculation Examination of the University of Melbourne is accepted by the Joint Board of Examiners of the Scottish Universities, as exempting from the Medical Preliminary Examination of the Scottish Universities, provided the examination includes all the subjects required under the regulations of the General Medical Council and prescribed by the medical ordinances of the Scottish University Commissioners (see the Students' Number of THE LANCET). With regard to the further question of the Junior and Senior Public Examinations of the University of Tasmania, these do not appear on the list of examinations accepted by the Board as exempting from the Medical Preliminary Examination; but we understand that the Secretary of the Aberdeen University Court will be asked to bring up the question of the recognition of these examinations at the meeting of the Board in April. In the event of any special cases involving hardship or requiring immediate attention arising in the intervals between the meetings of the Board there is an urgency committee empowered to deal with such cases on their merits.

A LEGITIMATE GRUMBLE.

To the Editors of THE LANCET.

SIRS,—Will you allow me to protest through THE LANCET against the discourtesy that prevails in our profession? I am one of that unfortunate genus *assistant*, and when applying for a post, although I send a full-stamped and directed envelope, not one in twenty gentlemen will take the trouble to return my photo and testimonials. I think myself lucky if I get 50 per cent. of my photos back, even after writing a second time for them. Mine, I find, is no exceptional experience, and it is a pity there is not a little more of that good old feeling amongst us—to do unto others as we would be done by.

I am, Sirs, yours truly,

Feb. 11th, 1895.

M.B.

. We have headed our correspondent's letter with a title which we consider apt to its contents. It may be complimentary to "M.B." that his photograph should in so large a proportion of cases be retained, but it is a compliment that has its drawbacks.—ED. L.

"CLUBS AND CHRONIC CASES."

To the Editors of THE LANCET.

SIRS,—Assuming the case one in which the patient has not broken the by-law in reference to contributing in any way to his illness, I should advise "Podagra" to ignore the society's definition of "gout" as a "chronic disease," and for two reasons: First, because if he allows the society to define such terms for him he might possibly find the precedence awkward at some future date. An insurance office on one occasion was desirous of disputing a death claim because the word "atheroma" occurred on my certificate. The insured had deceived them by not stating he was the subject of a "tumour or large swelling of the vessels." Secondly, because the local manifestations of the gouty diathesis are acute attacks, separate illnesses from time to time, and certainly entitling the poor sufferer to go on the funds. Ultimately no doubt the case will show some decided form of "chronicity."

I am, Sirs, yours obediently,

NATHAN HANNAH.

Ashton, Jan. 29th, 1895.

A QUESTION OF DOOR-PLATES.

To the Editors of THE LANCET.

SIRS,—Is it legal for a medical man who holds the following qualifications—M.D. Brux., L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S.G.—to have on one plate on his door "T. F. S.—, M.D." and on another plate "Dr. S.—"? I am, Sirs, yours faithfully,

Feb. 11th, 1895.

ENQUIRER.

. There is nothing illegal, we believe, in such a description, but we certainly think that under the circumstances two door-plates are quite unnecessary.—ED. L.

"QUALIFIED DISPENSERS."

To the Editors of THE LANCET.

SIRS,—Does the reply to "Chemicus" in THE LANCET of Feb. 9th respecting qualified dispensers imply that the Apothecaries' Hall qualification is not a legal one?

I am, Sirs, yours faithfully,

COLLOID.

Feb. 9th, 1895.

. What does our correspondent imply by the Apothecaries' Hall qualification?—ED. L.

CORONERS ON UNQUALIFIED PRACTICE.

To do prescribing druggists due justice, they generally do not tamper with their own children. Though they may indulge freely in unqualified practice they are usually alive to the advantage of medical advice when their own family is concerned. But a remarkable instance to the contrary has been partly exposed at Rotherham by the coroner, Mr. D. Wightman, in the case of William Eric Holmes, aged five years and a half, the son of Mr. Samuel Holmes, chemist, of Rotherham. Mr. Holmes was so satisfied with his own medical knowledge and wisdom that he treated his own child up to the time of his death. For eight or ten days the boy was ill, and even towards the end, when he "detected" signs of pneumonia, he did not send for the medical man. A neighbour was expecting him to call, and he asked her to send him in, but he did not call the first day, and Mr. Holmes simply repeated the request a second day through the neighbour. When he did call he found the child dead. Hence the inquest. The coroner made some strong observations on the conduct of the druggist; but not too strong. He dealt chiefly with the fact that by not calling in the medical man an inquest had been necessitated. This is the least objection to the course taken by Mr. Holmes. The greatest is that he did not give his child the benefit of medical attendance.

Durham.—The hard-and-fast line between the physician and surgeon cannot always be observed in provincial hospitals, but it certainly seems to us upon the facts put before us by our correspondent, that the surgical work should be strictly done by the men appointed by the governors to do it. Gynecological surgery is by common consent held to be a thing apart, and the rules or customs of different institutions dictate the different procedures.

Badge 17, 234.—We cannot do anything to practically display our sympathy.

"DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT."

To the Editors of THE LANCET.

SIRS,—In your interesting series of articles under the above heading you have not yet come to the point of payment. The clerk of a sanitary board refuses to pay me certain half-crowns on the score that I did not give him notice of the debt within a year. The Act does not order me to give such notice, nor has the aforesaid clerk till now informed me that such is necessary. Have I any redress?

I am, Sirs, your obedient servant,

Melksham, Wilts, Jan. 26th, 1895.

S. GROSE.

. Our articles have not attempted to deal with every individual case that might arise (see answer to "C. H. W. P."). There is nothing in the Act giving the clerk the position he has assumed, and our correspondent should communicate with his local authority. Perhaps the clerk's action is for convenience of audit.—ED. L.

"C A R A M E L S."

To the Editors of THE LANCET.

SIRS,—For the information of your correspondent, "M.R.C.S. (Retired)," in your issue of Jan. 26th, I quote the following from Roscoe's "Elementary Chemistry": "Sugar melts at 160° to a colourless liquid, which solidifies on cooling to a colourless transparent mass (barley-sugar) and on standing becomes crystalline and opaque. When more strongly heated, water is given off, and a dark-coloured mass, called caramel, is left behind." I have little doubt that this is the foundation of the caramels sold by confectioners, these being made of chocolate, white sugar, and butter boiled together in a pan and variously flavoured.

I am, Sirs, yours faithfully,

Sheerness, Feb. 4th, 1895.

JULIUS CÆSAR.

LEGAL REQUIREMENTS IN VACCINATION.

To the Editors of THE LANCET.

SIRS,—May I ask if there is any law or rule for a medical man in private practice to vaccinate any individual in more than one place?

I am, Sirs, yours faithfully,

Feb. 11th, 1895.

VACCINE.

. There is unhappily no binding rule.—ED. L.

During the week marked copies of the following newspapers have been received:—*Birmingham Argus*, *Midland Evening News*, *Star*, *Bradford Daily Telegraph*, *Judy*, *Dover Express*, *Newcastle Daily Chronicle*, *North Star*, *Brighton Argus*, *Western Morning News*, *South Wales Echo*, *Yorkshire Herald*, *Manchester Guardian*, *Perthshire Courier*, *San Francisco Chronicle*, *Lincolnshire Chronicle*, *Cheltenham Examiner*, *Cape Times*, *Falkirk Herald*, *Science Siftings*, *Cork Constitution*, *Yorkshire Evening Post*, *Sanitary Record*, *West Middlesex Standard*, *Reading Mercury*, *Local Government Chronicle*, *Weekly Free Press* and *Aberdeen Herald*, *Newcastle Daily Leader*, *City Press*, *Times of India*, *Architect*, *Pioneer Mail*, *Leeds Mercury*, *Yorkshire Post*, *Builder*, *Bristol Mercury*, *Guy's Hospital Gazette*, *Liverpool Daily Post*, *Scotsman*, *Herefordshire Mercury*, *Southern Times* (Weymouth), *West Middlesex Advertiser*, *Cork Examiner*, *Nature*, *Southampton Echo*, *Lancashire Evening Express*, *Local Government Journal*, *Lincoln Gazette*, *Matlock Visitor*, *Coventry Herald*, *Jarrow Express*, *Cornish Telegraph*, *Hampshire Advertiser*, *Kentish Mercury*, *Salford Chronicle*, *Perth Constitutional*, *Oswestry Advertiser*, *Somerset Journal*, *Worcester Chronicle*, *Forres*, *Elgin*, and *Nairn Gazette*, &c., &c.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.	
One Year	£1 12 6
Six Months	0 16 3
Three Months	0 8 2

POST FREE TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES ABROAD.

One Year	£1 14 8
Six Months	0 17 4
Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to Mr. CHARLES GOOD, Manager, THE LANCET Office, 423, Strand, London.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Hunterian Oration.

Delivered at the Royal College of Surgeons of England on Thursday, Feb. 14th, 1895.

By J. W. HULKE, F.R.C.S. ENG., F.R.S.,
PRESIDENT OF THE COLLEGE, &c.

MR. VICE PRESIDENT, VISITORS, FELLOWS, AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—We meet to-day to commemorate the 166th anniversary of the birth of John Hunter, that remarkable man whose name in this College is as a living presence, who did so much, and with such great success, last century to raise surgery from the lower grade of an empirical handicraft, which it then too greatly resembled, to the dignity of a branch of science by basing the principles that should guide its practice on the combined foundation of anatomy, physiology, and pathology. His great achievements as a surgeon, his life-history, and his personality have been so frequently and so fully dwelt on here that I may pass these by and at once take up the theme on which I would speak to you to-day. Its subject is John Hunter, the biologist, the sagacious investigator and interpreter of "organic nature." Of John Hunter in this character I can, however, offer you only a very incomplete sketch, since even if the time at my disposal permitted, and had I the necessary ability for such a task—a gift I may not claim—the materials for a complete presentment of him as a biologist do not now exist, for ten large bound volumes of manuscript, written mostly by his assistants at his dictation, and then revised, corrected, and added to by himself, embodying the records of the labours of many years, purchased, together with his museum, by the nation, which made our College their custodian, were about thirty years after John Hunter's death designedly burned by Sir Everard Home, his brother-in-law and executor. He, when interrogated respecting this act, asserted that he had destroyed these MSS. by John Hunter's expressed desire, as being by him considered too imperfect for the public eye. That these ten volumes of MS. were included under the words "Collections and everything belonging thereto," which John Hunter in his last will directed should be offered to the Government "in one lot," is not open to doubt; yet Sir Everard Home, shortly before the transfer of the "collections" from Leicester-square to Lincoln's-inn-fields, and, therefore, after their purchase by the Government, had them removed to his own house. The Board of Curators of the museum of the College appear not to have known that they had existed until after their destruction. This irreparable loss looms the larger when we study John Hunter's anatomical and physiological collections, when we ponder on the fragments of his writings rescued from destruction by the solicitude of William Clift, his devoted assistant and our first conservator, and when we read his lectures and other papers collected and published by this College and by Palmer, Ottley, and R. Owen. The better my knowledge of the extensive series of anatomical and physiological preparations, nearly all made by John Hunter's own hands—a series which may properly be regarded as the centre around which are clustered our own now very greatly extended and in some respects unsurpassed collection—the more profoundly am I impressed with the vastness of our great master's anatomical and physiological work, which, it should be remembered, was all accomplished within the relatively short space of thirty years, broken in upon by frequent and severe illness, and by the many interruptions incidental to the life of a practising surgeon; and the better my acquaintance with the Hunterian series the more am I impressed with John Hunter's sagacity, for in this series of preparations we have not the bald presentments of disconnected facts, but each preparation unfolds a tale, each conveys a lesson, each is a link in a chain, and not infrequently one clears up something which is obscurely represented or only hinted at by another. The overshadowing greatness of his zoological works perhaps accounts for the imperfect recognition by so many of us of how much John Hunter also occupied himself in botanical research. In one of several physiological papers, after discussing the agreements and the differences between that which the terms "common or original matter and animate matter"

—or, as we now should say, between inorganic and organic substances—and affirming the derivation of the latter from the former, for the reason that "animate is found to return to inanimate matter," he proceeds to analyse the resemblances and differences of the matter of which animals and vegetables are composed. He restricts "to vegetables the power of immediately converting common (i.e., inorganic) matter into their own kind"; and from this he draws the inference that a "vegetable seems an intermediate link between common and animal matter." In his lecture on the Principles of Surgery we find him reviewing the "accord" between the physiological endowments of vegetables and those of animals. He mentions that "a self-moving power has been observed and is universally allowed in vegetables"; and he adds that "this principle seems to be as much a property in vegetables as in animals." He illustrates internal mechanical work done within vegetable tissues by reference to Hale's notable experiments on the rising of the sap in trees, and he contrasts the magnitude of the force employed in this movement with that exerted in the heart's systole. Having defined "irritability" as the power of responding to stimuli by internal and external work, he draws attention to the visible movements of the "whole parts" of plants in response to external excitation as examples of this property. He instances the movements of the leaves of the leguminous plant *Hedysarum gyrans* as an example of this phenomenon; and he comments on an apparent analogy between these movements and those of respiration in animals suggested in their periodic repetition in both divisions of organic nature. He is, however, careful to avoid the error of attributing to these superficial resemblances an essential correspondence of function. With characteristic caution he says: "This—i.e., the recurring movements of the leaves—is an action apparently similar to breathing in animals, though, perhaps, it does not answer the same purpose." The circling movements of tendrils, as if seeking for a mechanical support, and their twining round this when they come into contact with it, did not escape Hunter's notice. Nor did he overlook the remarkable circumstance which characterises the twisting of the stems of certain climbing plants—viz., its constant direction for each plant. He notes the honeysuckle (*Lonicera*) and the hop (*Humulus*) as climbers, of both which he says: "Their stems turn to the left, whereas the stem of *Clitoria* and that of *Convolvulus* turn to the right." He instances *Dionæa muscipula* (Venus's fly-trap) and the *Mimosa pudica* (sensitive plant) as plants endowed with considerable powers of movement. He remarks that "the leaf of *Dionæa* upon being touched closes up, and, as it were, confines the stimulating cause"—that is, it entraps the insect which, in settling upon its upper surface, has touched the little cluster of extremely irritable hairs, there projecting above the general local of the cuticle. Of the *Mimosa pudica* he observes that it bends its leaflets in response to a gross mechanical stimulus, and also in response to the subtle excitation of varying quantities of light incident upon them. In connexion with this latter kind of stimulus, that of light, he mentions the goats-beard (*Tragopogon*) and *Calendula pluvialis*, two plants in the order *Compositæ*, and he says that they and many other plants close their blossoms towards night or at the approach of rain. Of this habit our indigenous centaury (*Erythræa*) and the scarlet pimpernel (*Anagallis arvensis*) furnish familiar examples. Then he proceeds to tell us that some other plants, as certain species of "convolvulus, open their flowers in the evening and close them at the approach of the sun." In striking contrast to these dusk-loving plants, John Hunter mentions that nearly the entire class *Diadelphis* (now designated *Leguminosæ*), which comprises, he says, "chiefly wing-leaved plants," close their "foliola towards night, not expanding them till morning," and he remarks that this phenomenon had been called by Linnaeus the "sleep of plants." This reference to the great Swedish botanist is interesting, because it proves John Hunter to have been acquainted with Petrus Bremer's remarkable treatise bearing the Latin title "*Somnus Plantarum*." It is included in the "*Amoenitates Academicæ*" of Linnaeus, published at Stockholm in 1759. In this instructive memoir Bremer asserts that "plants possess most qualities in common with animals—they feed, they have movement and rest, they have excretions, and they celebrate their nuptials." To Bremer we are indebted for an anecdote of the circumstance which first brought to the great botanist's notice the phenomenon of the folding of the leaves of certain plants at night, before unrecognised. Linnaeus, he tells us,

had placed in charge of an assistant a lotus (*Ornithopodioides*) and had enjoined him to take particular care of it. The lotus blossomed. Throughout the day its conspicuous blossom attracted notice, but in the evening, when the assistant visited the plant, the blossom, to his consternation, was not to be seen. The unhappy man, conceiving that the blossom might have been surreptitiously plucked by an evil-disposed person, watched the lotus more closely than before. Next morning a blossom again appeared; in the evening it had again vanished. Perplexed, and unable to account for the singular occurrence, but convinced that the blossom had not been stolen, the assistant hastened to tell Linnaeus what had happened. Linnaeus at once went to the lotus, and on closely inspecting it he detected the vanished blossom, still actually present, only hidden from view, mantled by the green leaves wrapt about it. Attention once aroused, the phenomenon was soon found to be common to many other plants. That it should have so long escaped recognition, and it should then owe its discovery to an accident, is but one of many instances we could readily adduce to show how easily do circumstances for which we are not looking pass unnoticed, even though daily occurring under our very eyes. John Hunter made the *Mimosa pudica* the subject of a study into which he threw himself with characteristic energy. He writes that "in order to have the greatest part of the day before me I began my experiments at eight in the morning while the leaves were in full expansion, and I continued them till four in the afternoon, as longer would not have been just, for they begin to collapse of themselves between five and six o'clock." With his peculiar aptitude for planning an experiment he contrived a small screen upon which he could trace and measure the arc through which a selected leaflet moved in response to a certain stimulus. In this way he found that "the leaflets are less affected as they become accustomed to the stimulus"; "that they require a stronger and quicker stimulus to produce motion after being some time accustomed to it"; and "that they erect themselves less after a repetition of such actions." Here the analogy to the corresponding occurrences in connexion with excitation of animal tissues is very obvious. Searching for the mechanism concerned in the movement of the *Mimosa* leaflets, John Hunter discovered that "the motion is principally confined to one part, and this differing from the others in external appearance, which difference is its increased thickness and uniformity of surface." Thus he locates the motor mechanism in the swelling at the base of the petiole, and in the homologous parts of the stalks of the leaflets. Next he tells us that he slit longitudinally the swelling on the "footstalk," and also that part of "the stem on which it stands," and he is about to record what he saw in these; but here, as Otley observes, there occurs a blank in the manuscript which leaves us ignorant of what he actually discerned in them. I do not gather from the context that John Hunter employed the compound microscope in this investigation. The contrary appears more probable, for the use of the microscope was then only dawning, and vegetable histology had made relatively little advance since Malpighi began to cultivate it in the latter half of the preceding century. We, at our standpoint, can hardly imagine the possibility of Malpighi holding concurrently the chair of Botany and that of Zootomy in his University (Bologna); yet in both these chairs he made discoveries which gained him enduring fame. We *medici* are wont to think of Malpighi as an anatomist only, whose honoured name has come down to us chiefly in association with certain minute bodies in the kidney, and in the spleen and a certain layer in the integument; but botanists revere Malpighi as the founder of vegetable histology. For John Hunter it may fairly be claimed that he pushed his investigation into the motor mechanism of the *mimosa* leaflets as far as was then practicable with the means at his command. Later investigators have demonstrated that when in a young, vigorous, succulent *Mimosa* a cut is made with a sharp knife in the petiolar swelling, dividing its parenchyma down to the central strand of vascular tissue, a drop of water oozes from the wound, upon which follows the well-known movement of the leaf. In the absence of this effusion of water no movement of the leaf occurs. Julius Sachs, who in recent years has done so much to advance the study of vegetable physiology, has further demonstrated that the visible leaf-movement is caused by the afflux of water in the petiolar parenchyma, distending this tissue and so causing it to become elongated more than the less extensible axile band of vessels. By such distensions of the mass of parenchyma

situated above the axile vascular band the upper part of the petiolar swelling is lengthened disproportionately to the lower part, and the leaf necessarily bends down; whereas, when the lower mass of the parenchyma is turgid with water the opposite occurs and the leaf is erected. By the device of removing first the upper mass of parenchyma and then the lower mass of it, Sachs was able to demonstrate that only the lower mass, below the axile vessels, is endowed with this irritability. It is now known that the movements of the *mimosa* leaflets are attended with the production of feeble electric currents. Such have been also demonstrated by Professor Burdon Sanderson to attend the movement of the leaf of *Dionaea muscipula*. Dr. Kunkel, working in Sachs's laboratory, has since demonstrated that weak electric currents accompany the movement of water in the vegetable tissues, however this movement is originated, and thus the generation of such electric currents is proved to be not peculiar to leaf-movements induced by external stimuli. Whilst experimenting on the *Mimosa*, John Hunter relates that he observed that when he touched the leaflets the visible effect of the local stimulus spread to the neighbouring leaflets, which he saw successively bend down in pairs until all the leaflets of the compound leaf were folded. He also noticed that this progressive effect of the stimulus spread from the point of its application more readily in the direction towards the stem than in the opposite direction towards the distal end of the leaf. Professor J. Sachs, and with him some others, appear disposed to regard the petiolar, axile, vascular bundle as the path along which the molecular disturbance initiated by the stimulus travels; but, whether this or the parenchyma is the path, it seems probable that a molecular disturbance in the living, active protoplasm is the efficient cause of the influx of water that produces the leaf movement. The protoplasm of adjoining vegetable cells is now known to be continuous through minute openings in the cell-wall, so that we are warranted in regarding the protoplasm in living vegetable tissues as a "continuum," and thus the propagation of a molecular disturbance to considerable distances from the point of application of a mechanical stimulus originating it becomes readily intelligible. John Hunter's experiments on the *Mimosa* were not restricted to the effects of mechanical stimuli. He also experimented on this plant with heat, with chemical solutions, and with ether. He tried also the effect of a tight ligature placed around the stem or branch, and he found that when the parts below the ligature were cut very slight or no movements of the leaf occurred. Continuing his discussion of the resemblances between animals and vegetables, John Hunter remarks that "vegetables are supposed, with great reason, to have an action analogous to breathing, for the same kind of air which kills animals which do breathe certainly kills vegetables also." He touches this subject so briefly that he leaves us uncertain whether he had himself experimentally investigated the influences of gases on plant life or had merely adopted the conclusions of others. This latter appears to me more probable when we remember the standpoint of the chemistry of the gases in his day. Carbonic acid gas was discovered by Black in 1767, nitrogen by Priestley in 1772, oxygen also by Priestley in 1774, and hydrogen by Cavendish in 1776, the year of John Hunter's Croonian Lecture, from which I have just quoted. We know that John Hunter and Cavendish were personally acquainted, for Hunter tells us that Cavendish examined for him "air" contained in certain bladders present on the intestines of a hog sent him by Jenner. There is, then, no improbability in the idea that Hunter may have derived from Cavendish his knowledge of the influences of gases on vegetable life. However this may have been, botanists have long recognised as a general principle the necessity of oxygen for vegetable life; that vegetables derive free oxygen from the surrounding atmosphere; and that they are also able to seize upon oxygen when presented to them in weak chemical combination. Of this latter action the reduction of oxy-haemoglobin to haemoglobin in the circulating blood by the bacillus of anthrax in animals dying of cattle plague has been regarded as a significant example. In the absence of oxygen plants are asphyxiated; vegetable protoplasm loses its irritability, though less quickly than does animal protoplasm, because the processes of vegetable life are less actively carried on than are those of animal life. When a plant is deprived of oxygen, as when it is placed in an atmosphere from which this gas is absent, during a short period the

want of the external supply of oxygen is in some measure compensated by the atmospheric oxygen previously enclosed in the air-spaces of the vegetable tissues; perhaps also some oxygen is derived by the plant from the decomposition of weak combinations of oxygen normally present in certain chemical substances contained in the tissues, but these sources of oxygen are soon exhausted. To this general law of the necessity of oxygen for the maintenance of vegetable life certain low forms seem to offer notable exceptions. Thus the yeast plant (*Saccharomyces cerevisiæ*) can live and even increase in an atmosphere devoid of oxygen. Its highest life-phase, however, requires the presence of oxygen, for it does not produce spores unless it has access to the atmosphere. Then, also, there are certain schizomycetes to which free oxygen appears positively deleterious—they die in its presence. The explanation of this remarkable phenomenon still awaits solution. The final products of the oxygen taken into the tissues of the plant are carbon dioxide and water. The former of these is exhaled from every part of the external surface of the plant. This, Von Tighem says, is the most constant phenomenon of plant life, and thus in the matter of gas-exchanges we find confirmed the impression mentioned by John Hunter as current in his day—viz., that a very close correspondence exists between vegetable and animal respiration. That plants, like animals, have “the power within themselves of producing or generating heat” was not unnoticed by John Hunter. He experimented also with freezing mixtures in order to ascertain the effects of very low temperatures on succulent and on woody plants, and he found greater resistance to cold in the latter. He also carried out a series of observations, prolonged over a year, on the internal temperature of trees relatively to the temperature of the external atmosphere. He mentions that he read his thermometers at six o'clock in the morning, and again at the same hour in the evening; and he mentions that he was obliged to discontinue the experiments because the sap froze in the bore-holes made in the trunks for the reception of his thermometers. He relates that he was careful to allow a sufficient interval to elapse between boring the holes and the insertion of the thermometer, in order that the heat produced by the friction of the gimlet might be dissipated; and he tells us that he enclosed the externally projecting part of the thermometer in a box and packed it in wool as a safeguard against “all immediate external influences, either of heat or cold.” We find, too, that John Hunter made a series of temperature experiments on vegetable seeds similar to others he had made on eggs, and he mentions his intention to record these. No record of them has, however, been found, and perhaps it may have been amongst the manuscripts burned by Sir Everard Home. John Hunter has left us a brief account of experiments in connexion with the movement of the sap. We possess also short statements of his views concerning the influence of light on the production of the “green colour” of vegetables; the changes undergone by the leaf when dying; the natural decay of the vegetable tissues; the morphology of the bud; and “germination and generation in vegetables.” I cannot now enlarge upon his work in connexion with these several subjects, nor is it necessary for me to do so, since enough has been said to justify me in claiming for John Hunter that he was a very close observer and an acute reasoner upon many of the phenomena comprised under vegetable physiology.

Leaving botany, John Hunter's title to a place in the foremost rank of original investigators in zoology, the other primary division of biology, is so universally acknowledged that more than a passing reference to his researches in the animal kingdom may seem unnecessary—particularly within these walls; yet on this occasion I may not dismiss them with a bare allusion. His memoirs on “The General Principles of the Blood,” on “The Vascular System,” on “Digestion, Absorption, and Nutrition,” and on “The Growth of Bones,” even at the standpoint we have reached, require attentive study. They show how far he was in advance of his contemporaries. John Hunter's devotion to physiology, which had its root in his conviction of the necessity of this “discipline” for the intelligent practice of surgery, was made a reproach by empirical surgical contemporaries, who called him a theorist and not a practical surgeon; indeed, his tardy recognition as a leading surgeon in the metropolis was probably partly owing to this wrong impression of him. One of his most important memoirs is certainly that on “The General Principles of the Blood.” From it we learn how much patient

investigation, how much concentrated thought, he gave to the striking phenomenon of its coagulation. “This,” he says, “is not a property of the blood as a whole, but only of one of its component parts—the coagulable lymph.” Then, with nice discernment, he makes the comment that “this would better be termed coagulating lymph, since blood serum also contains a coagulable substance, which, however, needs the addition of a chemical agent for its change from a liquid to a solid state.” Coagulable lymph—now termed fibrin—John Hunter regarded as the most important constituent of the blood, chiefly because he found it universally present in it. He sought to ascertain the influences of temperature on the coagulation of fibrin, and he proved that this is retarded by cold and hastened by heat. The effect of motion and of rest on coagulation also occupied his attention, with the result that he was led to regard rest as an important direct factor of coagulation, but not its immediate cause. The final outcome of his experiments and observations on the blood was the view of its coagulation, which I reproduce in his own words: “That the fluid state of the blood is connected with the living vessels which are its natural situation, and with motion; and that where there is a full power of life the vessels are capable of keeping the blood in a fluid state.” These views appear to harmonise closely with those of the present day. The red corpuscles of the blood, with whose appearances John Hunter was familiar, he considered a less important constituent than the “coagulable lymph,” for the reason that they are not universally present, not occurring in the colourless blood of the lower animals. The white corpuscles seem to have been unknown to him, a circumstance not surprising when we recollect how imperfect the compound microscope then was, and the entire absence of our numerous resources, of which I need cite only the use of differential staining agents by which so many delicate details of minute structure have been disclosed. How narrowly John Hunter scrutinised every unusual circumstance that came before him is shown by his remarks on “Liphæmia.” “The serum of the blood,” he says, “is often wheyish, and then upon settling it often throws up a whitish scum like cream.” “This was most probably first observed in human blood, but it is not peculiar to it.” He had noticed it “more frequently in the blood of breeding women, but he had seen it in others and sometimes in men.” Examined with the microscope he found this scum to be composed of “globular particles” which are not soluble in water and which rise to the top. This pathological condition of blood serum has in recent years attracted much attention; reference to it was made by more than one speaker in the “Discussion on the Morbid Anatomy of Diabetes,” an account of which was published in the Transactions of the Pathological Society of London.¹ Numerous and varied experiments were made by John Hunter to determine the cause of the different colour of venous and of arterial blood. He noticed the influence of respiration on the colour, and to the objection advanced by some persons, “that in the lungs the blood cannot come into contact with the air” he opposed the familiar fact that the bright red colour assumed by the outer surface of a blood-clot when exposed to the air “extends some depth into the clot,” whence “it is evident that air can and does pervade animal matter.” Passing to the “vascular system,” John Hunter notices the predominance of a muscular element in the coats of the smaller bloodvessels; and then he comments on the respective influence of the elastic and of the muscular tissue on the calibre of the vessel. He notices the branching and the anastomosis of arteries, and he discusses the effect of these arrangements on the velocity of the blood current. Then he investigates the pumping force of the heart in relation to the resistance offered by the arteries, the relative capacities of the venous and arterial systems, the retardation of the blood-current in the veins, and the form, structure, and distribution of the valves in the last-named vessels.

John Hunter's observations on “Digestion and Nutrition,” though much less extensive, are scarcely less instructive. I shall cite only one memoir—viz., that on “The Digestion of the Stomach (by its own Juices) after Death,” occasioning appearances which had previously been regarded as pathological, and respecting the true nature of which much acute difference of opinion continued long subsequently to exist, notwithstanding the thoroughness of Hunter's exposition. In a communication to the Royal Society made at the instigation of its President, Sir John Pringle,² John

¹ Vol. xxxviii., 1883. ² Read on June 18th, 1772.

Hunter insists on the prime importance of a correct knowledge of the appearances produced in the tissues of the body by those changes which they naturally undergo in those dying suddenly, as by fatal violence inflicted on persons in perfect health. He significantly remarks that in the absence of this knowledge appearances, collectively products of putrefaction, may readily be mistaken for others the results of disease, pathological in their nature and occurring during life, and thus confusion and misapprehension will arise. Then he proceeds to explain that "there is a case of mixed nature which cannot be reckoned a process of the living body nor of the dead; it participates of both, inasmuch as its cause arises from the living, yet it cannot take effect till after death." He adduces the fact that "animals or parts of animals possessed of the living principle, when taken into the stomach, are not affected by the powers of that viscus so long as the living principle remains. Thence it is that we find animals of various kinds living in the stomach or hatched or bred there; but the moment that any of these lose the living principle they become subject to the digestive powers of the stomach." His argument is that "if the living principle was not capable of preserving animal substances from undergoing that process [digestion] the stomach itself would be digested," which it is not. The "appearance" which John Hunter ascribed to post-mortem digestion is a dissolution of the stomach at its great extremity, in consequence of which there is frequently a considerable aperture made in that viscus. "The edges of this opening appear to be half dissolved, very much like that kind of dissolution which fleshy parts undergo when half digested in a living stomach, or when dissolved by a caustic alkali—namely, pulpy, tender, and ragged." At a loss to account for these appearances, John Hunter had supposed them to have been produced during life, and to have been the cause of death (then the current view); but the absence of associated symptoms and their frequency in persons who in health had died violent deaths occasioned him perplexity and made him "suspect that the true cause was not even imagined." He tells us that the first time he had observed this "appearance" was under circumstances that precluded its causation by disease—the man had just before his death taken a hearty supper of cold meat, cheese, bread, and ale. On opening his body a large hole was found in the stomach, through which part of the ingesta had escaped into the general cavity of the abdomen. Doubtful as to what this might mean, he began "many experiments on digestion on different animals, all of which were killed at different times after being fed with different kinds of food; some were not opened immediately after death, and in some of them [he adds] I found the appearance above described in the stomach." The memoir is worthy of study, if only as an illustration of John Hunter's method of work; whenever puzzled by anything of which the explanation did not immediately present itself he turned to experimentation for its solution.

These very incomplete references to some of his physiological researches show that, as an original investigator in this branch of biology, John Hunter was in line with the foremost workers of his day. How great an anatomist he was is evidenced by his published papers, by the value in which his lectures delivered in the Windmill-street rooms were held by those who made the effort to understand them and appreciate them, and is told even more eloquently by his "preparations" in our Museum. In anatomy, as I have already hinted, he was not a mere accumulator of facts, not a mere describer of figure, colour, and the relative positions of the organs and members of the animal body; but he ever sought for the explanation of these. He endeavoured to import into the art of anatomy the character of a science. He was ever seeking the how, the why, and the wherefore of the facts disclosed to him by his scalpel, ever reasoning inductively from particular instances and endeavouring to deduce general laws.

But John Hunter was not only a distinguished physiologist, zoologist, and anthropologist; he also assiduously prosecuted researches in embryology, previously little cultivated, and he gathered a rich harvest. How keenly, how penetratingly, he observed and how sagaciously he interpreted what he saw is apparent in his article on the "Development of the Chick." In order to ensure a supply of eggs for this research he kept large numbers of fowls and also a flock of geese during several years. John Hunter's labours passed beyond the limits of ontogeny, the development of the individual, to phylogeny, the evolution of the "stem." "We may

observe," he writes, "that in natural things nothing stands alone; that everything in nature has a relation to or connexion with some other natural production or productions; and that each is composed of parts common to most others, but differently arranged. Therefore, in every natural production there is an appearance of an affinity in some parts of its composition (with those of some other natural productions), and where there are the greatest number of these affinities (or corresponding parts) the correspondence or affinity between those of one production with those of another the nearer are those (natural productions) allied." In another passage, after premising that "definitions are the most damnable things," he defines "species" as "things having the same relationship in their most essential properties, however much they differ in others." So "animals breeding in the fullest extent of that process constitute the species, although this may differ in some of their parts or other circumstances, but which differences are less essential, only constituting a variety." He comments on the greater tendency of domestic species to variation than obtains in wild animals, which he illustrates by referring to the many diverse breeds of dogs and the few distinct races of wolves. This difference he attributes to the existence of domestic animals under other than their natural circumstances; in short, he recognises the plastic influences of environment. He perceives "in a great many species a considerable variety in the same, and from variety in the same species it becomes [he adds] a doubt whether they were all original or none of them, or, if any be original, which that one is." He alludes to the variability of species in more than one passage, and then makes the important comment that some variations are transmissible to offspring. He tells us that "it may certainly be laid down as one of the laws of nature for species to deviate from their type under certain circumstances"; and he significantly adds that it is neither necessary nor does it follow that all deviations from the original must be a falling off—it appears just the contrary; therefore we may suppose that nature is improving her works, or at least has established the principles of improvement in the body as well as in the mind." In these passages, laboured and somewhat deficient in perfect clearness of expression as they are, we find John Hunter enunciating the principles of the "inherent variability of species," of the "modifying influences of environment," of the transmissibility of variations from parent to offspring, and of evolution from lower to higher forms—in short, in those of his papers which escaped destruction there is to be found abundant evidence that his mind was often and deeply engaged in the consideration of the pregnant question comprised in the word "evolution" around which so much and such fierce controversy has been waged in our own day.

The significance of past forms of life did not escape John Hunter; he studied their fossil remains, of which he collected a considerable number. In a previous communication to the Royal Society on a series of fossil bones from caves at Galleereenth, presented to that body by his Serene Highness the Markgrave of Anspach, we find John Hunter investigating the circumstances of their fossilisation, comparing the form of these bones with those of extant animals, reviewing the geographical distribution of animals in past time, and drawing lessons from the *gisements* of fossils as to the condition of the earth's surface in past ages. From these and similar considerations John Hunter inferred a duration of our earth prolonged through "many thousand centuries." This chronology was so greatly at variance with that then universally received that a second memoir communicated by him to the Royal Society, in which he expressed this opinion, caused such misgiving in the council of that body that the suggestion was conveyed to John Hunter through a friend that he should substitute "years" for "centuries." With characteristic adherence to his convictions he would not modify his original statement and withdrew the paper.

John Hunter's researches were not limited by the walls of the dissecting-room, museum, and study; outside these he was a keenly observant student of living nature. To the great value of these two lines of work he was fully alive. In fragmentary notes on "Natural History" (edited by R. Owen) he remarks that "writers on the natural history of animals have been of two kinds, one [concerned] only in what they could observe externally, such as form and mode of life, the second [studying] only the internal parts and the structure of the whole animal, which was performed by the anatomist. As [the subject of] the first has an

immediate connexion with [that of] the second, the describers of form conjectured what the structure ought to be by consulting the works of the anatomist; and the anatomist conjectured what the living history is or ought to be from the natural history of others, filling up what he conceived to be just and fancy supplying the rest. But such union of knowledge does not properly match. It is one building built at different times—an addition to an original plan. It is no wonder, therefore, that the whole is imperfect." Can we pronounce all later anatomists and writers on natural history to be free from this reproach? John Hunter's remarkable memoir on the Life-history of Bees testifies to his excellence as a naturalist. For the convenience of close continuous observation of his bees without molesting them he had hives made with glass windows, which allowed him at all times to watch their occupants. He inquires into the causes of the deaths of certain bees in winter; he mentions that "there was plenty of honey in their hive; that on closely examining the dead bees he found they all died with their proboscides extended, their stomachs were full of honey, and their intestines, especially the last part, also full of excrement." No circumstance, however minute, eluded his notice. He comments on the heat of bees, and remarks that without warmth they become dull, inactive, and torpid. He tells us that "on July 18th, at ten in the evening, wind northerly, thermometer at 54° in the open air, I introduced it into the top of a hive full of bees, and in less than five minutes it rose to 82°. I let it stand all night. At five in the morning it was down to 79°, at nine in the same morning it had risen to 83°, and at one o'clock to 84°, and at nine in the evening it was down to 78°. Dec. 30th. Air at 35°, bees at 73°." John Hunter made the discovery that the wax is not gathered by the bees from flowers, as is "farina" (pollen), but it "is formed by the bees themselves." He says: "It may be called an external secretion of oil. It is formed between each scale on the under surface of the belly." He detaches the minute flake, warms it on the point of a needle in the flame of a candle, sees it melt and run into a bead, and then burn in the manner of wax—in short, it is wax. Then he describes the building of the comb and of the royal cell; the deposition of eggs by the queen, their attachment to the bottom of the cells, and their occasional transference from the cells in which they were first placed to other cells; the storing of bee-bread for feeding the grubs; the development of the grub, its pupal phase, and final escape from the cell as the imago. He notes the different life forms present in the community—the queen, the males, and "the working bee, which cannot be called either sex." Lastly, he describes the anatomy of the bee and comments on its special senses. With equal thoroughness he investigated the life-history and habits of the wasps and the hornets. We also find him occupied in a study of the economy and anatomy of the humble-bee (*Bombus terrestris*), on which subject he has left a long note. With untiring industry he examined all the occupants of one nest, and found them to comprise 157 females and twenty-five males, and he noted that the former had longer proboscides than the latter. The humble-bee does not, he tells us, colonise, like the honey bee; it does not swarm like these, but the family is begun by a single female, assisted later by her offspring. None but young queens live through the winter, on the approach of which they leave their nests and seek winter quarters in holes in dry banks and similar places, from which they emerge in the following spring. About May the humble bees construct their hives, which are usually beneath ground. He describes in considerable detail their structure, the deposition of the egg by the queen, the grubs which result from these, and their life-history, ending in the imago stage. The black humble-bee (*Anthophora retusa*) and the "leaf-celled bee" (*Megachile centuncularis*) were also objects of his study. He notices the habit of the latter of cutting pieces of the leaves of roses, strawberries, and figwood, and he admires the dexterity they evince in carrying these into their holes, and the skill and neatness shown in adapting them to the construction of their cells. His attention was not limited to the Hymenoptera, for we find him busy with beetles. Of the dung-beetle (*Geotrupes stercorarius*) he records that in June he found the grubs nearly ready to assume the pupal phase, and that the perfect beetle emerged at the end of July or in August. The nests enclosing the grubs are holes from twelve to eighteen inches below the surface of the ground, usually near cow dung. These and also other holes pierced for the purpose they use for winter quarters. Most of them die, but a few survive till

the following spring. Of the common cockchafer (*Melolontha vulgaris*) and the rose-beetle (*Cetonia aurata*) he has also left short notes. In Orthoptera he describes at some length the grasshopper (*Phasgoneuron viridissimum*), with special notice of the external appearance and the anatomy of its eye. He detects the predatory habit of the dragon-fly (*Esthna grandis*), concerning which he makes the following thoroughly characteristic note: "Aug. 18th, 1778, at eight o'clock in the evening, I saw the dragon-fly flying about, making short turns, which were performed very quick. I also observed gnats flying; and what took my attention most was his making up to a gnat, and the gnat was seen no more; therefore I conjectured he was feeding upon them. I caught him and opened him next morning, and could observe in the stomach the scales of some insects." What a picture this little anecdote gives of the acuteness of John Hunter as a field naturalist.

As a zoologist and morphologist John Hunter could not be satisfied with the highly artificial zoological classifications current in his day. He remarks on the want of an adequate knowledge of these preliminary and indispensable studies, which led even the great classifier Linnæus into some very singular arrangements in the earlier editions of his "Systema Nature," of which he notices one—viz., the placing together, in one order of mammalia, man, the elephant, and the bat, because in each the mamma are pectorally situated. Such classifying as this, he caustically observes, may be pertinent as regards nipples, but not as regards animals. He did not stop at showing the defects of the current artificial systems of classification of animals, but he suggested as bases for a natural classification the arrangements of the vascular, the respiratory, and the nervous systems; and he tentatively drew out the scheme of a natural classification founded on a combination of what he termed essential and circumstantial characters. Thus, of the class Mammalia he gives as essential characters a four-chambered heart, lungs confined in a proper cavity, the enlargement of which is the cause of respiration, lungs divided into small cells, respiration quick, viviparous, &c.; whilst circumstantial characters are found in the structure of the auditory organ. This illustration will suffice to prove how sound and how advanced were John Hunter's views as a systematic zoologist.

If in this sketch of John Hunter, imperfect, incomplete as I know it to be, I have succeeded in some small degree in presenting him to you as one of the most indefatigable workers, one of the most earnest seekers after truth, one of the very closest of skilled observers, one of the most sagacious expositors of vegetable and animal life, I shall not have altogether failed in accomplishing the design which I wished to offer you on this commemorative day—a presentation of John Hunter as a biologist in the widest sense of this now much-used word. For this I have made large use of his own words, because these best show his mind, and "the mind is the man."

The Aris and Gale Lectures

ON THE CENTRAL NERVOUS MECHANISM OF THE RESPIRATION.

Delivered before the Royal College of Surgeons on Feb. 18th
and 20th, 1895.

By WALTER SPENCER, M.S., M.B. LOND.,
F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AND TO THE THROAT DEPARTMENT, WEST-
MINSTER HOSPITAL; LECTURER ON PHYSIOLOGY IN THE
MEDICAL SCHOOL.

LECTURE I.

GENTLEMEN,—In these three lectures I propose to give an account of the nervous mechanism which produces respiration and to point out some of the practical uses to which this knowledge may be put. In doing so I have no wish unduly to separate this particular physiological action from the other vital functions of the nerve matter situated in the base of the brain. It is closely allied with the vascular mechanism and with the internal or tissue respiration producing heat. I began to make observations on this subject when I was collecting matter

for the essay on Intracranial Tumours and Abscess which received the Jacksonian prize. The work has been carried out at first at the laboratory of the Brown Institution and later in the pathological laboratory of University College. I am indebted to the Royal Society and also to the British Medical Association for grants of money towards the expenses of this research. My thanks are also due to Mr. Horsley for much help in connexion with the work.

HISTORY, COMPARATIVE ANATOMY, AND PHYSIOLOGY.

[The lecturer then gave a *résumé* of the views held about the respiratory function from ancient times down to Legallois, in whose works, published in 1830, the subject of the central nervous mechanism of the respiration was practically first treated. He then proceeded to consider the comparative anatomy and physiology of the respiratory function, and showed from specimens in the museum of the Collège how the alimentary canal is used for respiration (a) throughout its own length (a loach), (b) in its anterior part (salamander and amphioxus), and (c) by diverticula (gills or lungs). In certain fishes the air bladder is used as a storehouse for oxygen. In the higher animals muscles are used for respiration which in lower forms are either used for progression or are connected with the alimentary canal. Mr. Spencer then went on to speak of:]

The connexion of the automatic movement of respiration with the roots of the vagi nerves in the bulb.—In the pharyngeal form of respiration these nerves are both the afferent and efferent channel for the gill arches. In mammals it remains the chief afferent channel to the respiratory centre, but its efferent connexions are limited to the larynx, the facial nerve above being the channel for the nose, and as the muscles of the thorax take on a respiratory action efferent impulses go by the spinal cord.

The supremacy of the bulb over respiration and the subordinate influence of the spinal cord.—Legallois¹ was the first to show that an animal continued to breathe regularly after the removal of the cerebrum, cerebellum, and part of the bulb, so long as the section was made above the roots of the vagus group of nerves. On an injury to the origin of these nerves respiration finally ceased. The respiratory function was thus taken out of the category of voluntary movements, in which it had been previously included. Although respiration continues regularly for some time after section of the bulb immediately above the vagus roots, yet within a few hours the animal dies, for the highest centre for heat production and internal respiration and the vaso-motor centre are cut off, and thus a warm-blooded animal cannot live for any length of time. A section through or below the roots of the vagi destroys all respiratory movement except that of the nose and jaw. So long as the roots of the facial are intact² rhythmic movements of the nose and jaw occur during asphyxia—that is, when the facial nuclei have been quite separated from the vagi. The transverse section of the bulb immediately below the tubercula acustica abolishes all reflex sensory effects upon respiration from the cornea or nose, as well as the rhythmic movements of the nostrils—the facial muscles being either above the section or actually traversed by it. The first transverse section immediately affecting respiration runs just below the facial nucleus. The respiration becomes deeper and slow, with prolonged inspiration, just as after section of both vagi in the neck;³ in other words, the regulatory fibres of the lungs are connected with the highest part of the centre, and this fact has been confirmed by finding that the fibres enter the bulb by what is now called the "glossopharyngeal root." A transverse section at the level of the *alae cineræ* causes the respiratory movements to become irregular, sometimes periodic, and breathing comes to a standstill altogether by passing through the stages of asphyxia. Evidence as to a similar limit to the respiratory centre in man has been obtained from anencephalous monsters⁴ in which life has been prolonged even for four days. A fetus in whom the cerebrum and part of the cerebellum had been destroyed during birth continued to breathe regularly at the rate of six per minute after complete section of the

bulb by scissors 1 cm. above the calamus scriptorius.⁵ Bat a section immediately below the calamus abolished all respiration together with the reflexes. The effect of dividing the spinal cord below the bulb was known to Galen.⁶ He stated that when the spinal cord was divided between the first and second cervical vertebrae the animal immediately died, when between the third and fourth natural respiration was lost, and when below the sixth the diaphragm continued in action, the muscles of the thorax remaining stationary. After a section lower down the thoracic muscles were capable of movement. The effect of such injuries to the spinal cord are, unfortunately, too well known in man. Rhythmic movements of the facial muscles may continue for a long time if artificial respiration be intermittently performed. When the bulb is isolated⁷ by dividing it from the cerebrum, cutting the vagi nerves and the spinal cord below the sixth cervical vertebrae, the diaphragm continues in regular action. In a frog⁸ the cerebrum, including the mesencephalon, has been removed and the cord divided behind the atlas and destroyed, the lungs and even the heart extirpated, so that the bulb is entirely cut off from all peripheral influences, only 5 mm. of brain matter being left. Yet regular movements of the mouth, nose, and vocal cords go on, and traces of respiratory movement have been found so long as twenty hours afterwards. Experiments such as the foregoing seem to show clearly the supremacy of the bulb over the respiratory movement, and the unimpaired connexion of the spinal nerve roots with the bulb *a sine qua non*. Yet some have held the view that the ganglion cells in the anterior cornua of the spinal cord are the real sources of the movement, the bulb merely coördinating the whole. This opinion is founded upon the occurrence of rhythmic movements of the respiratory muscles after the separation of the cord from the bulb. They are seen in newborn animals⁹ which are kept warm, in animals of about six months when strychnine has been administered;¹⁰ in adult dogs after artificial respiration has been kept up from one to four hours.¹¹ In all these cases there is a very high excitability of the spinal cord, so that rhythmic movements of the limbs occur along with those of the trunk, and all reflexes are exaggerated. The rhythmic movements of the respiratory muscles in no way aid respiration. The animal dies as quickly when they occur as when they do not unless artificial respiration be performed. Indeed, there is no real inspiration¹² from enlargement of the thorax, for it is the muscles of extraordinary expiration which act strongly and without coördination, so that although the thorax may be rhythmically constricted it never dilates during such movements beyond the position of rest. The only positive evidence in favour of inspiration occurring after division of the spinal cord from the bulb is furnished by Langendorff's¹³ experiments upon the tortoise. After the division the inspirations as seen in his tracings become very much less and are followed by a forced expiration. If the small inspiration recorded be not due to some error in the experiment, such as the recoil of the lever beyond the position of rest after the forced expiration, one must admit that a small inspiration can be produced by the spinal respiratory centres of the tortoise. The arrest of respiration on section of the cord just below the bulb has been attributed to inhibition from the effect of the injury (shock).¹⁴ A much longer incision, however, can be made exactly in the middle line of the same region of the cord without affecting respiration, and a section above the roots of the vagi, were the arrest caused by inhibition, ought to have a like effect.

Brown-Séquard, however, in his last paper maintained the position he had always held—viz., that respiration was dependent upon nerve elements to be found throughout the base of the encephalon and cord. He laid special stress upon those cases in man in which a tumour involved the bulb, and in those in which a dislocation of the axis upon the atlas vertebra causes the odontoid process to press

backwards upon the cord. In such cases breathing continued for some time, although in some of the cases there was paralysis of the limbs and larynx. These cases of tumour in the bulb were many of them recorded long ago, and only scanty details are given as to the part of the bulb actually involved. Paralysis of the limbs simply proves the pyramids to have been affected, and the laryngeal paralysis may have arisen from pressure on the vagus roots. There has been no microscopical evidence to show that the region of the roots of the vagi were actually involved, and the tendency of slow growing tumours to displace nerve elements without robbing them of their functions is well known. A gradual dislocation backwards of the odontoid process narrows the foramen magnum antero-posteriorly without necessarily pressing on the lateral columns in which the respiratory tracts descend. Moreover, cases of dislocation of the odontoid process ultimately die from impaired respiration. If one were to assume that a specimen of a dislocated axis had reached the full displacement found post mortem without impairing the breathing, we should be unable to explain the patient's death and the impaired breathing which preceded it.

[Mr. Spencer then went on to consider the different connexions of the respiratory centre. In mentioning the discrepancies that obtain in the results of different observers, he pointed out how necessary it was that the degree of anaesthesia should be carefully recognised. He then continued:]

The respiratory centre can be affected by the excitation (a) of the vagi nerves, (b) of the cortex cerebri, (c) of all sensory nerves, and (d) of the floor of the fourth ventricle.

(a) *The vagi nerves.*—Owing to the differences in the description and nomenclature of the nerves passing through the jugular foramen considerable confusion has arisen. The nerves called glosso-pharyngeal, vagus, and spinal accessory outside the skull do not correspond in the composition of their fibres with the intracranial nerve roots which bear these names. Some have assumed that these nerves could be divided into a sensory and motor portion like a spinal nerve, whereas all evidence tends to show that the fibres outside the bulb are completely mixed. It is a matter for regret that the description given by Willis¹⁵ and illustrated in his drawing has not been generally followed. He speaks of the eighth pair of nerves as the vagi or wandering pair, using the word vagus in an anatomical sense. He likewise employs the term *accessorius* in its primary anatomical meaning to describe his spinal nerve as approaching and adhering to the vagus. The chapter containing his discovery of the nerve is entitled "Of the Spinal Nerve, an Accessory to the Wandering Pair." By many writers a physiological significance has been imported, as if the word accessory were used in its secondary sense of aiding the vagus. This error of using the term accessory in its secondary sense of aiding has led to the further error of applying this term to fibres which do indeed aid the vagus—viz., the lowest of the fibres arising from the bulb, which Willis included in the vagus. Thus the spinal accessory of one writer has a spinal origin, and the spinal accessory of another has a bulbar origin. I shall keep to the description of Willis and apply the word vagus to all the roots arising from the bulb. The spinal accessory nerve of Willis is quite distinct from the vagus, both in its origin, in its course, and in its distribution to the sterno-mastoid and trapezius, and finally, as I shall show, in its structure. It is absent in fish and snakes, whilst in other reptiles, amphibia, and birds it varies according to the development of the neck muscles to which it is distributed. The vagi, on the other hand, are constant in all vertebrates, arising from the lower half of the bulb in a well-developed form. By careful dissection the spinal nerve of Willis can be easily separated from its adhesions to the lower roots of the vagus. In man, no doubt, the fibrous sheath is tough and the nerves have generally softened from post-mortem decomposition. But in the stillborn foetus I have found no difficulty in separating the spinal accessory away from the vagus by simply using needles. The same can be done in the species of monkey (*Macaca rhesus*) I used in my experiments, in a gibbon I dissected at the Zoological Gardens by the kindness of Mr. Beddard, in a chimpanzee which had been experimented upon by Messrs. Beever and Horsley, and also on one contained in the college stores. In the rabbit, horse, mule, ass,¹⁶

and dog, all the roots from the bulb are intimately united, and the spinal accessory runs distinctly apart. Undoubtedly in the cat there is a closer adhesion between the spinal accessory and the lower bulbar roots. I have under the microscopes specimens of the nerves in a monkey. The nerves were hardened *in situ*, cut whilst embedded in paraffin, and stuck on the slides before the paraffin was removed. It will be seen that the spinal accessory nerve of Willis is similar in structure to the hypoglossal, whilst the vagus roots all resemble in structure the white rami communicantes of the sympathetic system of nerves. That the vagus roots should resemble the sympathetic rather than other cranial nerves is not surprising. In the cyclostomes the vagi include the sympathetic and extend to the anus. Even in higher mammals there is no sharp boundary between them. The ganglion of the trunk of the vagus is closely connected with the superior cervical ganglion, there is an intimate connexion in the anulus of Vieussens, in the cardiac and pulmonary plexuses, and lastly in the abdomen, where the fibres of both completely intermingle. The sections and drawings which I show you illustrate the following points. The spinal accessory nerve of Willis as well as its separate roots consists entirely of large medullated fibres collected into a compact nerve with hardly any connective tissue and nuclei separating its fibres. It is thus similar in structure to the hypoglossal. Where it is adherent in the jugular foramen to the lowest vagus roots it is separated from them by a distinct connective tissue sheath. It shows no ganglion cells on any part of its course. The size of the nerve before it adheres to the vagus roots is the same as when it has separated to go to the muscles. There is a gap between the uppermost of its roots and the lowest of those from the bulb, between which the posterior cerebellar artery runs backwards.¹⁷ All the vagus roots have the same character. They consist in the main of small medullated fibres with a few large medullated fibres scattered among the smaller ones. Separating the fibres in each root is a considerable amount of connective tissue and nuclei. Moreover, all have ganglion cells upon them. From the roots nearest to the nerves down to the lower end of the bulb there is no gap between the several roots. It is only as the roots approach the foramen that they become gathered into separate trunks. The lower vagus roots have a number of ganglion cells upon them. In the section of each root there is at least one ganglion cell to be seen.¹⁸ These roots are gathered up together and become applied to the dorsal and anterior part of the spinal accessory, but, as aforesaid, separated from it by connective tissue. The spinal accessory afterwards separates completely. These lower root fibres communicate with the ganglia on the main vagus trunk, but it does not completely fuse with the latter until the lower end of the ganglion of the trunk of the vagus. The upper and middle roots are collected into two trunks as they enter the jugular foramen. Each has a ganglion upon it, and in the foramen these two ganglia become intimately united. Thus, microscopical examination distinctly separates these roots from the spinal accessory nerve of Willis, and shows that there is no gap in the origin of all the vagus roots, that they are similar in structure, and are intimately connected in or just beyond the jugular foramen.

LECTURE II.

THE FUNCTION OF THE VARIOUS ROOTS OF THE VAGUS, ESPECIALLY OF THOSE AFFECTING RESPIRATION.

[Mr. Spencer commenced by giving reasons for his choice of the monkey to experiment on, and gave a short description of his methods. He continued:]

If I place the results hitherto obtained in a tabular form it will show the chief functions of the vagus nerve roots in order from above downwards; but this order must be taken in a very general sense. There is, as I have shown, no gap in the nerve roots coming from the bulb. It is, therefore, very easy for the electrical current to spread or for injury to be done to adjacent roots in the attempts made to divide or separate them. Even if such a division into upper, middle, and lower vagus roots be granted, yet different observers will not make exactly the same divisions. With all due allowance

¹⁵ Willis, Thomas: Works, ch. xxviii., p. 141, tables 9 and 10. London, 1684.

¹⁸ Remak: Forleips, Neue Notizen, 1837, No. 54, p. 150.

for this the following table roughly expresses the results hitherto obtained:—

Table of the Functions of the Vagus Roots.¹⁹

	Afferent.	Efferent.	
Vagus.	Upper roots = "IX. nerve"	Regulatory fibres of respiration (lung). Fibres exciting respiration (inspiratory). Superior laryngeal.	Cricothyroid. Stylopharyngeus. (Esophagus. Pharynx (constrictors).
	Middle roots = "X. nerve"	Fibres inhibiting respiration (expiratory). Bronchial (cough).	Gastric. Bronchial (muscular). Inferior laryngeal. Cardio-inhibitory. Levator palati and azygos.
	Lower roots of bulb		Sterno-mastoid and trapezius.
Spinal accessory nerve of Willis = "XI. nerve"			

The fibres which come from the lung enter through the highest roots, for the division of these roots produces the same changes on respiration as does that of the vagi in the neck. The first transverse section across the bulb which involves the respiratory centre has also this effect. If these fibres be stimulated when anaesthesia is slight the effect is an excitation of respiration. Should the stimulus be greater there is a tendency to arrest in inspiration or over inspiration. Excitation of the middle vagus roots in not too deep a stage of anaesthesia produces cough, in a deep stage arrest in expiration. No doubt if a stronger current be employed in a monkey completely anaesthetised, arrest in expiration can be obtained from any of the vagus roots, yet the middle roots always arrest with the weakest stimulus. Stronger currents tend to spread and are therefore a source of fallacy. If the proximal end of the middle roots be excited the same arrest in expiration occurs as when the fibres are stimulated in continuity. When the distal end is excited after division the larynx is closed by the adduction produced, and thus the respiration is rendered slow and laboured as by excitation of the recurrent laryngeal nerve itself. The weakest current affects the cardio-inhibitory fibres. In the monkey a current with the secondary coil 16 cm. distant from the primary has a greater influence on the heart than the excitation of the vagus in the neck with a current 8 cm. away from the primary coil. Those fibres which most readily inhibit the heart are the lower roots of the vagus.

ON THE INTIMATE STRUCTURE OF THE CENTRE OF THE BULB.

It is chiefly by experiments such as those just described that our knowledge has been extended with regard to the physiology of the bulb itself. The nature of the experiments made upon the bulb have been chiefly cutting operations, and therefore liable to produce complications. Thus Flourens and Laborde²⁰ found that an animal could be instantly killed by removing the layer of grey matter at the calamus scriptorius, which is exposed by the separation of the posterior median columns of the spinal cord. This "nœud vital" experiment must, however, produce its result through neighbouring structures, for the bulb and upper part of the spinal cord can be divided down the middle line,²¹ including the calamus, without arresting respiration on either side. Other experiments have been equally contradictory, the "intermediary bundle,"²² the "ascending root of the ninth and tenth nerves,"²³ two groups of cells²⁴ nearer to the middle line than the hypoglossal roots, the "dorsal nucleus" of the pneumogastric,²⁵ a circumscribed zone in the formatio reticularis lateralis²⁶ external

to the hypoglossal roots have each in their turn been claimed as the essential seat of automatic respiratory movement. In young animals²⁷ the roots of the nerves going to respiratory muscles are supplied from both sides of the bulb, so that a hemisection at the upper end of the cord causes only a temporary or slight impairment of respiratory movement on the side of the lesion so long as the origin of the phrenic nerve is not injured. In order to avoid the complications produced by injuring the bulb I have made a number of observations on the excitation of different points of the floor of the fourth ventricle. The floor was exposed by removing a portion of the occipital bone and then raising the middle lobe of the cerebellum or actually removing it in part or wholly. The results have served to confirm those just described on the vagus nerve. At the level of origin of the upper vagus roots respiration may be excited and over-inspiration may be produced. At the level of the middle roots, if the animal be in deep anaesthesia, there is always arrest in expiration, behind this at the level of origin of the lowest vagus roots cardio-inhibition.

The cerebrum and respiration—Whilst experimenting upon the fourth ventricle I found that respiration could be affected by excitation of the floor far above the roots of the vagus. Recognising that this must be due to the stimulation of the fibres descending from the cerebrum to the respiratory centre I turned to the research which is described in the last number of the Philosophical Transactions under the title of "The Effect produced upon Respiration by Faradaic Excitation of the Cerebrum in Monkey, Dog, Cat, and Rabbit."²⁸ No definite results had been obtained by previous observers, the animals having been either too deeply or insufficiently narcotised. Munk²⁹ alone had some results which as far as they go were confirmed by my own. Christiani³⁰ and also Martin and Booker³¹ found respiration to be influenced from the mesencephalon, especially at the side of the hinder end of the third ventricle and the aqueduct of Sylvius. They supposed their experiments to show respiratory centres in the mesencephalon, but I have no doubt that they stimulated the tracts leading from the cortex to the respiratory centre in the bulb which I am about to describe. As a result of a number of experiments upon the four species of animals—cat, dog, rabbit, and monkey—by excitation of the cerebral cortex, and the surfaces of cerebral sections carefully made in a vertical plane backwards to the bulb, I found four different results, each obtainable from a distinct area on the cortex, and traced each back along a definite line. These four effects I will proceed to illustrate by photographs and tracings, and it will be seen that they are such as can be produced upon the respiration by means of the will. (a) The first effect is that which leads to a diminution of action on the part of the respiratory centre, and finally to an arrest. Slowing consisted in a definite diminution of the rate of respiration during the time of the stimulus, and if the strength of the stimulus were increased there was an immediate arrest of the rhythm. This arrest might last for a minute or more if the stimulus were strong enough. Generally respiration started again at the previous rate immediately on the cessation of the excitation. If the stimulus were insufficient it might only momentarily arrest it. The cortical area from which this result was obtained is situated upon the frontal lobe just outside the olfactory tract, anterior to the point where it joins the temporo-sphenoidal lobe, as indicated by the crossing of the Sylvian artery. The same result was obtained along the line of the strand of fibres known as the olfactory limb of the anterior commissure. After decussation in the latter structure the tract continued backwards by the side of the infundibulum into the red nucleus below and external to the aqueduct in the plane of exit of the third nerve. That the strand of fibres on either side decussates in the middle line may be shown by making hemisections backwards until the anterior commissure be reached. Before the hemisections have reached the level of the anterior commissure the cortex of the sound hemisphere still retains its power of arresting respiration. When, however, the hemisections pass the anterior commissure the cortex of the sound side loses its excitability, but arrest can then be obtained from the mesial out surface of the anterior commissure. The fibres affecting respiration are thus excited just

after decussation. The character of the arrest varied in different stages of anaesthesia—the deeper the anaesthesia the greater the tendency to arrest in expiration; in lighter anaesthesia arrest was either in full inspiration or in over inspiration.

(b) The other effects found have the tendency to increase the action of the respiratory centre in the medulla. The respiratory rate may be greatly accelerated, but what is gained by acceleration may be partly lost by diminution in amplitude. This diminution does not neutralise, however, the increase of rate, because apnoea may be produced in this way. In an imperfectly anaesthetised animal any excitation of a sensory surface may tend to cause some acceleration, but the tracings in my animals show that this is a very marked acceleration of the rate unaccompanied by any irregular movements. The cortical area on which the greatest acceleration can be obtained lies around the upper end of the infra-orbital sulcus in the dog and cat. In the rabbit the point is marked by a vessel which comes up between the mesial edge of the hemisphere and the falx cerebri, and then turns out over the convex surface, grooving the surface of the cortex in a line which suggests correspondence with the crucial sulcus in the cat and dog. Marked acceleration is obtained on either side of the vessel at the edge of the hemisphere. The position is similar in the monkey—viz., about the sulcus X. The acceleration may be followed back through the lenticular nucleus, where it borders on the outer ventral portion of the internal capsule. The strand runs at first externally and then ventrally to the motor portion of the internal capsule and so reaches the tegmentum. The lines from the two sides meet in the interpeduncular grey matter at the level of and just below the plane of exit of the third nerve. A hemisection in front of the exit of the third nerve does not remove the acceleration effect from the cortex of the remaining hemisphere. On the other hand, a hemisection immediately in front of the pons does so.

(c) Another increased action of the respiratory centre can be obtained, resembling that made by snuffing. The four species of animals reacted in a similar way. The animal first made an over inspiration, then several sharp over inspirations were super-imposed and followed the primary one. These over-inspiratory jerks were peculiar in following one another at regular intervals in a rhythmic manner, and not ceasing exactly at the same time with the stimulus, one, two, three, or more over-inspirations taking place after the cessation of the stimulus. To this movement I have given the term over-inspiratory clonus. Each over inspiration was followed by a sharp expiration, during which the thorax did not reach the position of equilibrium—that is, there was no action of expiratory muscles. This effect was obtained from the mucous membrane of the upper part of the nose, from the olfactory nerves, bulb, and tract. On applying the stimulus in a line backwards along the olfactory tract, this snuffing movement was traceable to the uncinate convolution of the temporo-sphenoidal lobe. From the uncus it passed behind the optic tract to the crus, and thence obliquely inwards underneath the crura. Thus the tract on each side converged to meet in the middle line at the upper border of the pons. Excitation of this point was the only place on the section where this result could be obtained.

(d) The fourth effect which can be obtained from the surface of the cerebrum is a widely generalised one, because it can also be got by the excitation of any sensory nerve. The chest assumes a position of over inspiration by means of the tonic contraction of the extraordinary muscles of inspiration, but the rhythmic movements of the ordinary muscles continue in a regular manner. If an excessive stimulus be used the over-inspiratory spasm produces a pseudo-arrest by masking the rhythmic movements. But the latter can be seen to continue, only obscured by the tetanic spasm. The sensory motor area on the cortex and the descending motor tract specially yield this result. It can also be got from the fifth nerve and from the sciatic after complete removal of the cerebrum at the level of the tentorium cerebelli.

SUMMARY OF THE AFFERENT CONNEXIONS OF THE RESPIRATORY CENTRE.

Sensory nerves of all kinds tend to excite the respiratory centre in the direction of inspiration, any acceleration of the rate being due to the will, and, therefore, not obtainable in anaesthetised animals. If the stimulus be too strong the thorax is driven into an over-inspiratory spasm, but the respiratory rhythm is here not really arrested except by the

spasm of other muscles counteracting those of ordinary respiration. Such inspiratory spasms are seen in any wide excitation of the skin, such as by cold water, tickling, and in the first stage of drowning. When the spasm comes to an end in the last case bubbles of air escape from the mouth. This inspiratory³² spasm in the first stage of drowning is not dependent on the will, for it takes place in a narcotised animal; nor is it due entirely to the cold, for it takes place in water at the temperature of the blood; neither is it wholly due to inhibition from the larynx, for respiration is arrested in rabbits although a tube may have been previously placed in the trachea and its free end kept above water. The vagus nerve in the neck contains inspiratory fibres which enter the bulb through the upper roots. The centre of the sensori-motor area of the cortex is likewise influenced in the same way—e.g., in epileptic fits. This inspiratory influence through sensory nerves is entirely lost in deep anaesthesia, so that the strongest current applied, for instance, to the fifth nerve has no effect on respiration. The respiratory centre can be inhibited, its rhythm slowed and arrested in expiration, and the chest remains motionless in the position of equilibrium. This takes place by electrical excitation of the fibres entering by the middle roots of the vagus, by excitation of an area on the cortex cerebri and of a tract connecting this area with the medulla, and by excitation of the floor of the fourth ventricle. The deeper the anaesthetic the more readily is the inhibition obtained uncomplicated by inspiratory influence. Acceleration of the rhythm apart from the influence of the will of the animal is far more marked on the cerebral cortex and on a tract leading down to the bulb. Probably it is difficult to get such acceleration from the floor of the fourth ventricle on account of the simultaneous excitation of inhibitory influences. From the nose two forms of excitation may pass back to the respiratory centre—an inspiratory tonic effect through the fifth nerve and an inspiratory clonic effect through the olfactory nerves and brain. No inhibition of respiration was obtained from the nose in anaesthetised animals. The arrest of respiration which other observers have noted has happened in animals fully awake. When tobacco smoke or chloroform is blown into the nose of a rabbit it holds its breath. The will is the cause of the arrest in this and other powerful sensations which can be perceived by the animal.

Over-action of the respiratory centre.—The respiratory centre can be stimulated by changes in the composition of the blood supplied to it: (1) by excess of carbonic acid; (2) by deficiency of oxygen; (3) by an increase of oxygen, especially if the centre be failing; (4) by an increase in the temperature of the blood; and (5) by the products of muscular metabolism.

1. An excess of carbonic acid gas in the air breathed begins to cause hyperpnoea when it reaches to 3.5 per cent.³³ This is about the amount contained in expired air. In air containing about 5.5 per cent. breathing has to be as deep as possible, and at double the normal rate. If the amount of carbonic acid gas be greater distress becomes marked when the carbonic acid gas amounts to 10 per cent., even although there be an ample supply of oxygen. If, however, the carbonic acid be mixed with oxygen—air in which oxygen has not been diminished—7 per cent. of carbonic acid can be for a time inspired without harm. The hyperpnoea thus excited by the carbonic acid introduces sufficient oxygen.

2. Reduction of oxygen to 12 per cent. excites respiration, but not to the extent of the corresponding increase in carbonic acid. Marked hyperpnoea is caused with 9 per cent. of oxygen. When reduced to 7 or 6 per cent. there is a tendency to loss of consciousness, paralysis of limbs, and impairment of breathing. We are well acquainted with this diminution of oxygen in the course of the administration for anaesthesia of nitrous oxide or nitrogen gas.

3. An increase of oxygen tends to stimulate a failing respiratory centre. The administration of air restores the respiration to the normal; oxygen in a more concentrated form produces general excitement and stimulates the respiratory centre so much that apnoea does not occur.

4. A most powerful stimulant to the rate of rhythm and to its depth is a slight increase in the temperature of the blood flowing through the bulb. Either the blood in the carotid

may be warmed or the animal may be overheated.³⁴ Thus in an experiment when the temperature in the vagina or rectum was 39.8° the rate was 42 per minute, at 41.1° C. 142.³⁵ A dog with a rectal temperature of 39.2° C. and a respiratory rate of 20 per minute was placed in a chamber at 73° C., when the rectal temperature rose to 40.8° C., the respiratory rate quickened to 50 per minute, more than double the amount of air passing in and out per second. During this acceleration by heat the animal cannot be made apnoëic, and moreover shows great resistance to narcotic poisons. Thus morphine or chloral may be given in a sufficient dose to lower the rectal temperature and impair the respiration. On the application of heat sufficiently to raise the rectal temperature 1° C. above the normal the respiration rate may be doubled.³⁶

5. The centre is further excited by the products of muscle metabolism. Afferent stimuli being excluded by division of the spinal cord, the tetanising of the muscles of the hind limb³⁷ causes an increase in the respiratory rhythm, whilst the oxygen and carbonic acid in the blood remain normal. Thus during work increased respiration keeps the amount of oxygen and carbonic acid in the blood normal. In the horse the amount of oxygen taken in and the carbonic acid given out is enormously increased during movement, the respiratory quotient not altering as compared with that during rest.³⁸ The walk increases the respiratory interchange about two and a half times, the trot five times that of the rest; in the gallop ten to twenty times more air is taken in and given out.³⁹ This enormous increase in respiration is connected with the diminished alkalinity of the blood⁴⁰ from an excess of lactic acid produced by muscular activity. This acid acts as a direct excitant to the respiratory centre of the rabbit.⁴¹ The carbon dioxide diminishes the alkalinity of the blood, and the excitation which it causes may be an instance of the same kind—viz., the excitation of the centre by a weak acid. In diabetic coma not only lactic acid but acetic and oxybutyric acid⁴² have been found in the blood. When sugar in sufficient quantities to affect a dog is injected lactic acid is found in the blood. Diabetic coma and rapid tissue changes in fevers may, therefore, have a double excitatory influence on the respiratory centre by diminishing the alkalinity of the blood, as well as by raising its temperature.

Diminished action of the respiratory centre.—The action of the respiratory centre may be lowered: (1) by diminution in the amount of carbon dioxide in the blood, provided that this is not neutralised by excess of oxygen, or of temperature, or of the products of metabolism—this diminution may be due to removal by forced artificial respiration or by a diminished production of carbon dioxide; (2) by excess of carbonic acid (asphyxia) and poisons (anæsthetics &c.); and (3) by impairment of the circulation through the centre, whether by failure of the heart, by vaso-motor paralysis, or by increase of intracranial pressure.

*Apnoea.*⁴³—Forced artificial respiration by removing more carbonic acid from the pulmonary alveoli causes the blood to become of a more scarlet hue. If this be done with air at the temperature of the room the animal is rapidly cooled. Long apnoëic pauses are obtained when the centre has been depressed by the cooling. After artificial respiration for one minute a pause may follow for twenty-five to thirty seconds, after artificial respiration for two minutes a pause of two minutes, or for ten minutes after artificial respiration for half an hour. At the end of the apnoea the blood has lost its bright colour and natural breathing begins. After making a number of deep respirations the length of time during which a man can hold his breath can be extended from a quarter of a minute to one minute or more. The conditions, however, are not exactly the same as in experiments upon animals, for whilst holding the breath expiratory muscles gradually compress the air in the lungs and so favour the entrance of oxygen, as in the Cetacea. (See below.) When we turn to other conditions in

which apnoea occurs—viz., the apnoea of the fœtus, that existing during hybernation, or in those apparently dead—we must take into consideration the important relations which the central nervous mechanism of the respiration has with that of the heat regulation or internal respiration,⁴⁴ and that of the vaso-motor mechanism. The mechanism of heat regulation in warm-blooded animals is intimately connected with respiration, for the excess of CO₂ given off in the production of heat must be got rid of. But before birth and for a variable time after birth the animal is more or less cold-blooded—i.e., has not yet developed a complete heat-regulating mechanism.⁴⁵ Thus new-born mammals such as rats, mice, and puppies react like cold-blooded animals, their temperature sinks towards that of the surrounding medium, and at the same time there is a corresponding fall in the amount of CO₂ given out. Soon after birth they gain a heat-regulating mechanism, which becomes so established that when placed in an atmosphere colder than themselves they give out more CO₂ and maintain their temperature. Thus in young blind mice about three days old on a fall of temperature from 30° to 20° C. there is a lessening in the discharge of CO₂ within thirty minutes to about one half; a few days later, on the other hand, there is a rise in the CO₂ given out under similar circumstances. A chick in the egg reacts like a cold-blooded animal, its temperature falling with that of the medium and less CO₂ being given out. It reacts like a warm-blooded animal after hatching, and it has then control over its muscles and is able to run about. A pigeon when hatched is blind, naked, and helpless, one of the parent birds is constantly sitting over it and feeding it, and when exposed to cold it reacts like a cold-blooded animal.

The human fœtus⁴⁶ when born, especially if before term, rapidly cools if exposed to a medium much lower than that of the blood, less CO₂ is produced, and the respiratory centre may not be excited. Hence the answer to one of the questions put by Harvey: Why does a fœtus born in its membranes not breathe? Being like a cold-blooded animal little CO₂ is produced, and the circulation passing by the ductus arteriosus is not obstructed in attempting to pass through the lungs. Life—that is, the circulation—has been said to last in a new-born child, especially before term, for fifteen hours without any apparent respiration. These infants may show after death evidences of injury such as ecchymosis &c.⁴⁷ On the other hand, the normal respiratory centre at term is sufficiently excitable to be stimulated by any increase of carbon dioxide above the amount existing in the circulation of the mother. If the abdominal aorta of a pregnant animal at term be compressed the fœtus begins to gape and inspire in the liquor amni. As in apnoea produced by inflation, so also in the apnoea of the fœtus a sufficient excitation to the skin may produce one inspiration, but is not the cause of the commencement of rhythm. An apnoëic fœtus responds to external stimulation by an inspiration, whereas one which has become asphyxiated does not. Whilst under normal circumstances an increasing venosity of the blood is a sufficient stimulus to the centre, yet if the centre be weakened from any cause it may fail to respond to the venous blood, therefore death may occur without any attempt at breathing. The circumstances of a long labour by hindering the circulation of the fœtus may gradually impair the centre, whereas if the venosity of the blood comes on rapidly without any preliminary exhaustion of the circulation a fœtus must inspire whether before or after birth.

When the fœtus has once breathed it must continue to do so. Oxygen, entering with the first breath, raises the excitability of the centre and at the same time stimulates internal respiration, whilst the distension of the lungs from their previous atelectatic state diverts the circulation through them. After the first breath an arrest of respiration places a mechanical hindrance in the way of the circulation, which has now to pass through the lungs. Further also, the more active metabolism increases the amount of CO₂ given off. Hence the answer to Harvey's second question—why it cannot dispense with respiration when once it has breathed—is to be found in the increased excitability of the respiratory centre and the larger amount of CO₂ given off from the tissues. Instead of apnoea asphyxia then occurs. Whilst in an apnoëic fœtus an external stimulus may cause it to take

one inspiration and so introduce oxygen, this method must compare unfavourably with artificial respiration, in which there is not the danger of mechanical injury. Exposure in a cold room or the application of cold water, by lowering the temperature, impairs the centre. In a state of asphyxia the fœtus will not respond to external stimuli, and then artificial respiration is the sole remedy, aided always by external warmth—an important adjunct—applied by a hot bath or especially to the neck.

In hibernating animals the absence of respiration is accompanied by a great fall in the production of carbon dioxide. They become cold-blooded, the temperature falling almost to that of the air; at the same time the circulation becomes very feeble. A hibernating marmot or dormouse can live in an atmosphere of CO_2 in which a bird or rat perishes instantly.⁴⁸ The respiratory centre is in them in a stage of apnoea, a marmot pinched during hibernation gives an inspiration. A raising of the temperature of the medium excites respiration, the animal recovers its normal temperature, and circulation and muscular activity.

A rapid production of carbonic acid in a warm-blooded animal produces asphyxia, paralysing the respiration. Two influences may delay the onset of asphyxia—a large amount of blood holding a good stock of oxygen, and an increased tension of the oxygen in the lung favouring absorption. The respiration in the Cetacea⁴⁹ forms an interesting example in this respect. In them internal respiration must be enormous to maintain a body temperature of 37°C ., and they are very active animals. They are characterised by having a circulatory apparatus and an amount of blood much in excess of a land animal of the corresponding size. Seals can remain under water for five minutes and whales for a much longer period, yet the time they spend at the surface is exceedingly short. A dolphin at rest in an aquarium breathed three times a minute. It began with a rapid forced expiration through the vent for one second, the return to the position of equilibrium and an inspiration lasted another second, and this was followed by a pause of eighteen seconds. This pause is really an inspiration during which, the vent being closed, the air is subjected to pressure from the chest walls. In this way oxygen can pass from the lungs into the blood during the time the animal is under water. The excessive amount of carbon dioxide which has collected during the pause whilst the animal is under water is got rid of by the forced expiration. It is by imitating this respiration of the Cetacea that men can dive and remain under water in active movement. To show the value of the store of oxygen in a large amount of blood Paul Bert⁵⁰ compared the behaviour of a fowl plunged under water with that of a duck. A fowl plunged under water is soon distressed, the inspiratory inhibition gives way, bubbles of air escape, the bird loses consciousness, and falls on its flank with a loss of the corneal reflex in about two minutes. It makes a series of inspirations, the last accompanied by rigidity, and in about three minutes is dead. The duck can remain under water, simply struggling to escape, for seven minutes after immersion without expiring. Its heart beats much slower, and may even fall in rate from 100 to 14 per minute, showing that carbonic acid is collecting, but the conjunctival reflex remains, and consciousness is preserved. The want of oxygen is not felt for seven, ten, or even fifteen minutes, then the animal loses consciousness and its reflexes, lets air escape, falls on its side, makes some inspirations, becomes convulsed, and dies. The behaviour is the same in the two birds, when the trachea is clamped, the fowl dies within three minutes and the duck lives from eight to sixteen minutes, so that the delay cannot be attributed to the custom of diving on the part of the duck. The lungs and air sacs are similar in the two birds. Weight for weight, however, Paul Bert found the duck to contain one-third more blood than the fowl. If about half the blood were first taken from a duck it died as quickly under water as a fowl.

THE governors of the Farringdon General Dispensary held their annual meeting on Feb. 12th at the offices in Holborn, Mr. Lacy, the treasurer, presiding. The patients during last year numbered 24,286. The total income for the year was £730. The Hospital Sunday Fund and the Hospital Saturday Fund made grants of £43 and £11 respectively, and a donation of £25 was received through Alderman Treloar. The balance in hand at the end of the year was £109.

Jettsonian Lectures

ON THE

COMBINATIONS OF MORBID CONDITIONS OF THE CHEST.

Delivered at the Medical Society of London on Feb. 18th, 1895,

By FREDERICK T. ROBERTS, M.D.,
F.R.C.P. LOND.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AT UNIVERSITY COLLEGE; PHYSICIAN AND PROFESSOR OF CLINICAL MEDICINE AT UNIVERSITY COLLEGE HOSPITAL; CONSULTING PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

LECTURE III.

CLINICAL LESSONS; INVESTIGATION OF CHEST CASES.

Symptomatology.

MR. PRESIDENT AND GENTLEMEN,—Although in my last lecture I placed physical examination in the forefront in relation to the investigation of combined chest cases, I by no means wish to give it undue prominence. On the contrary, I feel it necessary to utter a protest against a practice which is not at all uncommon—namely, to be content with finding out in this way what physical changes or conditions, if any, exist, and looking at the case solely from this standpoint, estimating its importance simply by the presence or absence and the degree of such changes. This is a dangerous error, and I now urge the imperative necessity of an intelligent study of the symptomatology in every instance, and of endeavouring to understand the phenomena complained of or observed in their relation to the morbid conditions present. I say “study” advisedly, as distinguished from a mere enumeration of chest symptoms, which is of little value, as it may apply equally to any number of thoracic cases which are essentially different in character.

I have already pointed out that there may be practically no symptoms even when very pronounced and complicated morbid changes are present in connexion with the chest. This negative aspect, however, must not be overlooked; for it may be highly significant as indicating the pathological nature of these changes, showing that they are not, at any rate, of a serious character in themselves, and that they do not materially interfere with the important thoracic contents. But I have now to deal with chest symptoms from their more positive aspect; and I am anxious to indicate as clearly as possible certain points which, in my opinion, are of the greatest consequence in relation to the subject which forms the basis of these lectures. In the first place, it must be remembered that the thoracic structures are closely related to each other, anatomically and physiologically, as well as pathologically, and it is a great mistake to separate too definitely the symptoms associated with particular organs. It must be familiar to any intelligent clinical observer that there is no actual line of demarcation between the symptoms due to pulmonary and cardiac diseases respectively, and when we have to deal with complicated conditions any distinction of this kind becomes absolutely impossible and mischievous. Under these circumstances it is imperative that they should be studied on a thoroughly comprehensive basis, in order to understand their practical relations and significance. In an acute or sudden case the study of local chest symptoms is of the utmost importance, and may reveal the presence of conditions or disturbances which cannot possibly be determined by physical examination, especially when the state of the patient does not allow such examination to be carried out efficiently. The phenomena, even of individual acute diseases, as described in text-books, are by no means always typical; but when we have to deal with the various combinations to which I have previously referred, they become still less characteristic. It is under these circumstances that the study of the symptoms becomes particularly instructive. The severity and characters of pain and other morbid sensations, the kind of disturbance of breathing and the various noises associated therewith, the peculiarities of the cough and expectoration, and other symptoms, are all worthy of attention, and often reveal important features of the case. The varieties of so-called “dyspnoea” demand special study, for they are often most significant, and we may have to found our diagnosis

of certain conditions very much on what we thus observe. When circumstances permit, and especially in dealing with chronic cases, I think it is a good rule to start by finding out, approximately or even fully, by physical examination what conditions are present in connexion with the chest, and then to study systematically the symptomatology, both comprehensively and individually, in relation to the sum total of these conditions. It must always be remembered that in complicated cases most of the symptoms are either produced or modified by more than one, it may be several, factors; and it is decidedly to our patient's interest and advantage that we should find this out as precisely as possible. A known combination of certain morbid conditions will often prepare us for the occurrence of sudden attacks or accidental lesions, so that we ought to recognise without difficulty the symptoms by which they are respectively revealed.

I wish now to draw special attention to the essential importance of a single symptom in relation to diagnosis in some cases of a mixed character. And here let me urge the great value of the senses of hearing and smell in the detection and recognition of certain of these symptoms, in addition to the exercise of the faculty of keen observation. Let me illustrate this point by two or three examples. A particular kind of disorder of breathing or the characters of a cough may certainly reveal to us at once not a few individual conditions; the characters of the materials expectorated are also often highly significant, and the sudden discharge of a quantity of pus may be the one indication of the bursting of an empyema into the lung, or of certain kinds of abscess into the air passage, of the existence of which we might previously not have been aware. To the sense of smell I have been indebted on several occasions for arriving at an immediate diagnosis as to the presence of conditions which had previously been absolutely overlooked. I allude, of course, to the offensive or foul odour which the expired air may yield under certain circumstances, especially after a vigorous cough. This has revealed to me bronchiectasis in highly emphysematous lungs, which could not possibly be detected by physical examination, as well as gangrene of the lung in obscure cases, and obvious pyo-pneumothorax, which a careless and limited examination of the upper part of the chest had failed to detect. With regard to the sense of hearing, this is of essential value, altogether apart from auscultation, in recognising peculiar characters of, or sounds associated with, the acts of breathing and coughing, as well as alterations in the voice. I have several times been enabled to make an immediate diagnosis in cases of obscure intra-thoracic aneurysm on these data, some of which had even been admitted into the hospital wards as cases of asthma. One case was so extremely interesting, and taught me such a lesson, that I venture to describe briefly what happened.

A good many years ago, during the early period of my connexion with the Brompton Hospital, on returning home, physically tired and mentally exhausted, after a hard day in the out-patient department, I found a man waiting for me with a letter from a lady asking me to see him (gratuitously, of course) as he was suffering from bronchitis. I told him that I was not fit then to examine him properly, and asked him to come in the morning. It seemed to be a mere case of ordinary bronchitis and emphysema, but, fortunately for me, the patient gave a slight cough, and I instantly perceived that it was one of the obscure cases to which I have previously referred, in which an aneurysm presses directly on the trachea. I told him to go home at once to bed and that I would come to see him in the morning. Before I could do so, however, I received a message that he had begun to spit blood, and within twenty-four hours he died from profuse hæmoptysis, the aneurysm having ruptured into the trachea.

Another aspect of the symptomatology of chest diseases which is of essential importance, but is often regarded very casually, is the relation of general or remote symptoms to these affections, especially when they are of a combined character. Here again I must content myself with merely offering two or three prominent illustrations. The occurrence, type, degree, mode of progress, and associated phenomena of fever are often most significant. Thus we may recognise not only pronounced inflammatory or tuberculous cases, but also those indefinite changes going on in the lungs to which I have previously referred. Moreover, by the presence of fever we may be led to conclude that there must be some obscure condition within the chest, as, for instance, a localised collection of pus, which is entirely out of reach of direct examination. In cases of phthisis I need scarcely say that pyrexia is a most valuable indication as to the activity and progress of the disease. But perhaps one of the most striking

illustrations of the diagnostic value of this pathological state is when malignant endocarditis supervenes upon old chronic disease of the cardiac valves, which it may be impossible otherwise to recognise. General wasting is another symptom which is very instructive, as indicating what is going on in the chest, not only in relation to phthisis, but also to other conditions, especially obscure cases of malignant disease, particularly when it involves the pleura. Anæmia, likewise, often deserves thoughtful attention. The phenomena resulting from obstruction of the general venous circulation, notably dropsy, always demand careful study. It is a very common tendency to associate these phenomena simply with heart disease. Let it be remembered, however, that this is by no means their sole cause, and that they may be very pronounced when the heart is practically normal, while in cardiac cases they are often aggravated by pulmonary conditions. This class of symptoms, especially dropsy, is often of great help in determining what is the actual state of things in connexion with the heart, and here it may be particularly noted that functional disorder superadded to organic cardiac disease is often accountable for the occurrence of dropsy or for its temporary aggravation. I will only further state that general symptoms not uncommonly add more or less to the troubles immediately connected with the chest, especially by disturbing the breathing and the cardiac action. The relation of the pulse to morbid conditions of the chest opens up a very wide subject upon which I cannot now attempt even to touch. I will only say that, regarding it merely as a symptom, and without reference to any elaborate methods of investigation, it affords in a large number of instances most valuable diagnostic information about combinations of these conditions which I do not think is always adequately appreciated. I may, by the way, draw attention to the fact that the absence of the radial pulse on one side is another important point to be remembered in relation to the diagnosis of an obscure intra-thoracic aneurysm. I have incidentally referred to certain of the minor structures contained in the mediastinum in my preceding remarks. I wish now merely to point out that interference with these structures, or their implication in actual organic changes, is chiefly indicated by what may be regarded as mere symptoms as distinguished from physical signs. These may be merely modifications of the ordinary chest symptoms, to which, however, they give special characters, such as pain, cough, respiratory disorders, or cardiac phenomena; but some are of special kinds, such as dysphagia due to obstruction of the œsophagus, or signs of implication of the sympathetic nerve, of certain veins, or of the thoracic duct.

Special Methods of Investigation.

It would obviously be impossible for me to deal at any length in these lectures with the various methods which are employed at the present time in the investigation of morbid conditions of the thorax and its contents. I can only indicate their general nature, and say a few words about each in its relation to my subject. Those to which I propose to refer are: 1. Examination of the sputum. 2. The use of certain instruments and other apparatus for particular purposes. 3. Operative procedures. 4. Examination of the larynx and trachea. 5. Examination of the œsophagus.

1. *Examination of the sputum.*—When carried out in a rational manner, there can be no doubt whatever that systematic examination of the materials discharged by expectoration is of the utmost value in many chest cases of a more or less combined nature, by giving us definite information about special pathological changes and conditions associated with the respiratory organs. I have already alluded to certain points relating to the general examination of the sputum, but I take this opportunity of saying that such simple examination is often most instructive, and it is by no means carried out to the extent which, and as methodically as, it ought to be. Of its chemical examination I can say nothing from personal knowledge. As to its microscopical investigation, this is so thoroughly familiar to everyone nowadays that I almost blush to mention it. I will only venture to hint that it is always desirable to carry it out with intelligence and judgment, and that it cannot invariably be relied upon, either from its positive or negative aspect. At the same time I fully recognise its importance, not only in relation to the detection of tuberculous lesions, but also in revealing destruction of the lung tissues, gangrene, actinomycosis, and other conditions, of which we might otherwise have no definite knowledge.

2. *Use of instruments, &c.*—There is undoubtedly a

tendency at the present day among the more scientific members of our profession, especially what I may call the "advanced juniors," to make use for clinical purposes of different kinds of apparatus, not uncommonly of a very elaborate kind, which no doubt give more accurate information about various details relating to the size and conformation of the chest, or the respiratory and circulatory functions and movements, than can otherwise be obtained. Personally I have always had a strong inclination towards simplicity in examination, and have never cared for employing elaborate instruments of any kind, nor do I hesitate to affirm that as a rule they are not required. At any rate, I must again express my opinion that no instrument ought to be allowed to take the place of the trained and educated senses of sight and touch, used in a simple and intelligent manner. With the ordinary kinds of apparatus coming under the present category no doubt you are all familiar, but if you want information with regard to some of the more recently introduced instruments I may refer you to the Goulstonian Lectures for 1894, on the "Physics of the Circulation," by my friend, Dr. Paul Chapman of Hereford, and to the recent work on "Pulse-gauging" by my old friend and fellow-student, Dr. George Oliver of Harrogate.

3. *Operative procedures.*—I must not encroach upon the domain of the surgeon, but I feel bound to point out the essential value of certain operative procedures in the investigation of not a few more or less complicated chest cases, which I have on many occasions found of the greatest service under such circumstances. I allude more particularly, of course, to the use of the exploring needle or trocar, and other measures intended to demonstrate the presence and situation of fluid in either serous cavity, as well as its nature, or the existence of an obscure abscess in the lung or elsewhere, or of a hydatid tumour. More serious operations may be demanded for diagnostic purposes in exceptional instances, but to these I need not further refer.

4. *Examination of the larynx and trachea.*—The inherent importance of laryngoscopic examination in relation to certain intra-thoracic diseases is so well known that I need scarcely do more than mention it. Not only does it directly reveal associated morbid states in the larynx or even in the trachea, especially tuberculous and syphilitic; but the signs produced as the result of interference with one or other of the laryngeal nerves may be almost the only data upon which we can positively recognise an aneurysm or growth obscured by other conditions within the chest. Similar signs may be associated with an adhesion and fibroid thickening in a case of old chronic apical phthisis. I may also allude here to "tracheal tugging," a sign which Surgeon-Major Porter has shown to be of real service in the diagnosis of deep-seated aneurysm.

5. *Examination of the œsophagus.*—In relation to this form of special examination I will merely remark that it may be useful, not only in the investigation of morbid conditions of the œsophagus itself, but also of diseases in its vicinity. Obviously it requires the aid of a skilful manipulator.

REMARKS ON TREATMENT.

It must appear a very rash and irrational procedure on my part to launch out into the vast subject of treatment at the conclusion of these lectures; and yet I cannot resist the inclination to make an attempt to deal with it from certain general aspects in its relation to the combinations of morbid conditions of the chest. Of course, I shall say but little about therapeutic methods or agents, and my object is simply to bring into prominence a few broad principles or indications, which I think need to be specially enforced at the present time, and which my subject obviously and fairly suggests.

1. The management of chest affections is far from being such a simple and easy matter as many people seem to imagine, and they certainly cannot as a rule be dealt with as individual entities, to be severally treated on a routine and settled system or plan, or with a particular remedy, varying according to the age in which we happen to live, the prevailing therapeutic fashion or fad, or the personal, and it may be very peculiar and original, views of the individual medical practitioner or "scientific therapeutic." Still less ought we to be content with merely treating symptoms—a practice but too often habitually adopted—sometimes, indeed, with remarkable success and undeserved kudos, for the man who acts on this principle, and who does not take the trouble to investigate his cases, will often administer powerful drugs, with benefit, it may be, when they are in reality very dangerous, and when a

well-informed practitioner, who had ascertained the facts of the particular case, would not dare to use them. In the long run, however, this method of procedure is certain to do infinite harm, and to lead to lamentable results, of which but a very small proportion actually come to light; and not only is it directly mischievous and dangerous, but it does infinite harm by allowing serious morbid conditions within the chest to progress unchecked, which might often be arrested, or at any rate controlled, in their early stages, if their presence had been properly detected. And here I must enter an emphatic protest against a state of things extensively prevailing, and with which as a profession we are deeply concerned, that not only permits, but encourages in a high degree, the evil against which I have been speaking—namely, the prevalence of "cheap dispensaries," where so many patients are polished off within the hour; the employment of ignorant unqualified assistants; and the encroachment of the "prescribing chemist" on the domain of the medical practitioner. We do occasionally see in the newspapers some startling revelations brought out in the coroner's court, but these only give a faint hint as to what is actually proceeding on a very large scale. These revelations, however, do not lead to any change, and things go on just as before.

After this digression I return to my point, and must insist on the fact that a large proportion of chest cases, even when they belong to a particular category, must as a necessary consequence of their combined conditions present more or less difficulty in their management, and that they ought always to receive due consideration from a therapeutic as well as a diagnostic standpoint. Sometimes the difficulties are very great, and we may be able to do little or nothing for our patient. But while fully recognising this aspect of the question, I affirm, on the other hand, that much can often be done, even in highly complicated cases, in the way of treatment, if we study them adequately and intelligently, and deal with the existing conditions rationally and judiciously.

2. Now, the first thing we have obviously to determine in relation to the treatment of combined chest conditions in a particular case is what we can and what we cannot do. We are bound to face the uncomplimentary fact that there are morbid changes which we cannot influence materially, or perhaps not at all, and we had therefore better leave them alone. Of course there are grave diseases for which we can do absolutely nothing, and then I think we ought to be very cautious in using powerful drugs or practising special methods of treatment, the good results of which are, to say the least, highly problematic, though of course it is impossible to lay down any "hard-and-fast" rule in this matter, and each case must be dealt with on its merits.

There is another class of cases, of very common occurrence, in which permanent changes in various combinations affect the chest and its contents, not necessarily immediately dangerous or serious in themselves, but which give rise to more or less troublesome symptoms, and yet we can do little or nothing for them directly. Under these circumstances our main indication is to try to get the patient to understand the state of things, to learn to put up with and make the best of them, accommodating himself or herself to existing conditions, and to ward off further evils by judicious care, and avoiding doing foolish acts which are likely to bring on additional troubles. I must say that patients do not like this kind of advice, and as a rule resent our ignorance and incompetency, but really it is often the best and most honest advice that we can give, and in the long run many come to acknowledge this fact. A large number of cases coming under this category merely present the combination of minor changes to which I referred in my first lecture. Others belong to the group, and a very trying and sad one it is, where individuals who have led a too active and energetic life, and who often boast that "they have never had a day's illness," are unexpectedly found out and pulled up by the development of one or more prominent chest symptoms, or by some sudden serious disturbance, and it is then discovered that more or less grave morbid conditions have been slowly but surely progressing for some time, of which these phenomena are the outcome and manifestation. To bring such patients to reason, and to make them understand that they must give up their hunting and shooting, their mountain-climbing, their boxing and fencing, their lawn-tennis, or even their golf, is anything but an easy task for the medical practitioner. Even the "old man" who has long passed his "three score years and ten," and has had a "real good time" in every respect, cannot understand why he should

come to the "end of his tether," and that not even "hypodermic injection of spermine" can infuse new life into him.

There is still another class of cases to which I must allude here—namely, those in which definite and easily recognised chronic morbid conditions exist in the chest, in various combinations, but entirely inactive and quiescent, though no remedies or methods of treatment can modify them in the least degree. There are hundreds and thousands of cases of this kind, to which we apply particular names, and which throng our hospital out-patient rooms, where I venture to affirm that no active treatment at all is needed, and indeed such treatment is often worse than useless. And here let me say a word as to the frequent necessity of a more judicious use of applications to the chest. By way of illustration I may call attention to the fact that to go on applying some preparation of iodine—sometimes, too, with not very pleasant results to the patient—day after day, and week after week, for the supposed purpose of "absorbing" something which cannot possibly be absorbed, such as a greatly thickened pleura or a densely fibroid lung of long duration, is at least not "scientific therapeutics." Of course this procedure may be of service as a "placebo," or to relieve a symptom, when judiciously carried out, but that is altogether another matter.

A very important matter in relation to the classes of cases I am now discussing is that, although any active treatment may be decidedly contra-indicated, the prevention of any further chest complication is of the greatest consequence, and more or less stringent measures towards this end have often to be carried out. Obviously, climate comes in here as a valuable therapeutic factor, but due care is necessary even under the most favourable climatic conditions. Moreover, the great advantages of "home treatment" must also be duly recognised in this connexion, the good effects of which may be very striking. I have already alluded to patients suffering from chest affections who are able and willing to remain indoors all the winter under comfortable conditions, and thus not only prolong their lives considerably, but often manage to have a by no means unenjoyable time. But they are not all so amenable to reason, and what one finds is that not a few individuals, suffering, it may be, from even serious chest diseases, want to enjoy all the amusements and fun that are going on in the world, without any regard to the risks involved, and they expect us, in our professional capacity, to avert all the evils which their imprudence brings upon them.

From the point of view I am now discussing, in-patient hospital treatment becomes an inestimable boon, even in a "hospital for consumption," with all its supposed risks, and my personal observation and experience will bear ample and emphatic testimony in support of this statement. At the same time, in the light of modern researches and observations, I fully admit that it is our duty to take every possible precaution to prevent tuberculous infection; and it may be a question whether it is desirable to bring phthisical patients in whom the disease has been practically arrested and cured into too close contact with those who are suffering from the complaint in an active form.

The next point worthy of notice is that in the cases we have been considering, should any complication supervene, even if it be but a slight cold, it ought always to receive immediate attention. Neglect of this principle is accountable for much serious mischief.

3. I now proceed to say a few words about the treatment of combinations of diseases or morbid conditions of the chest in acute cases, as they come before us in practice, and for which we are expected to do something definite. Obviously it is impossible to lay down any distinct general rules, but every case must be studied individually, bearing in mind the recognised principles which usually guide us in dealing with the several acute chest affections. It is especially desirable in these cases to try to realise fully at the outset what conditions we have actually to treat and what we propose to do by our therapeutic measures. I think the general tendency is rather to be too active than the reverse, and it is well to lean to the side of discretion. A routine line of treatment directed only to one factor in an acute combined case, say pneumonia, is decidedly to be avoided. The supervention of acute or pronounced chronic conditions often gives us a very trying case to manage, and if the combination is not understood it will probably be a bad time for the patient; if nothing worse happens he is pretty sure to be subjected to a more energetic treatment than the circumstances demand. Of all the cases that harass the medical practitioner and make him feel his smallness and

impotence I think there are none worse than those complicated acute inflammatory chest cases of rapid onset and progress, to which I referred in my previous lecture. Some of them are obviously hopeless almost from the first; in others we feel that we must make a fight for life, and there is no greater satisfaction than when, by sticking to our patient and encouraging others to do the same, we succeed, aided by intelligent, judicious, and devoted nursing, in bringing the conflict to a favourable issue, and, humanly speaking, save his life. Unquestionably the rational administration of medicinal agents becomes in these cases of the highest value, especially of those which affect the functions of the vital organs, or which assist or modify expectoration. I cannot now refer to other details of treatment, and will only say that it is in grave, acute chest conditions that we derive such timely help from active therapeutic measures intended for special purposes, more particularly abstraction of blood, either by venesection or local methods, or even by cardio-centesis, free dry-cupping, inhalation of oxygen, artificial respiration, or subcutaneous injection of powerful drugs, such as ether, strychnine, or digitalin. How far the injection of antitoxins is going to be of service to us in the future in the treatment of formidable acute inflammatory diseases of the contents of the thorax remains to be seen, but so far as diphtheritic cases are concerned I can affirm that the results which have been achieved in my wards at University Hospital, under the active management of my late house physician, Mr. Bunch, are most satisfactory, and fully bear out the favourable reports from other quarters.

4. The actual treatment of chronic chest cases which come before us, presenting such a variety of morbid conditions, in every conceivable combination and not uncommonly highly complicated, is a problem that always requires thoughtful consideration, and often gives abundant scope for the application of sound therapeutic knowledge and skill, guided by discretion and judgment on the part of the individual practitioner. As I have already intimated, many cases of even pronounced chronic chest diseases do not require any active measures at all—at any rate, as a constant or regular practice; but in others we can do much, by the administration of suitable remedies or in other ways, to influence or control morbid processes, to relieve or help symptoms, or to affect temporary conditions or disturbances which so often form part of the history of these cases. Of course general or constitutional, as well as climatic treatment, and that directed to the digestive or other systems, is frequently of essential importance, and I must draw special attention to the great value, not uncommonly, of more or less prolonged rest in bed from time to time, particularly in cardiac cases. As regards the use of medicines, I think the tendency is to overdo things in this direction in chronic cases, even when they are needed, and I may observe that sometimes we find a condition present which distinctly contraindicates the use of a particular drug, or at any rate should make us very cautious in its administration—as, for example, extensive pericardial adhesion, which certainly is not favourable for the employment of digitalis and allied agents. It is interesting and important to note that if one has the opportunity of watching the progress of chronic chest cases of a combined nature, it will frequently be found that they present exacerbations of symptoms from time to time, which pass away under treatment, but in many of them a period comes when nothing further can be done, and the patient must inevitably succumb. The laity cannot understand this at all, and do not see why what has been accomplished before cannot be done again; and I must say that occasionally even a medical man does not quite realise the state of things under these circumstances, but expects the "consulting physician" to achieve impossible results.

5. I now come to the consideration of a definite principle in the treatment of combined chest cases of all kinds, be they sudden, acute, or chronic, as well as indeed in those of a simple nature, and one which I regard as of the greatest consequence. It is this: to be always on the look-out for, and prepared to deal more or less actively with, certain morbid conditions, often of a pronounced kind, which we can materially influence by treatment or even absolutely get rid of, but which, if allowed to continue, are sure to lead to serious results, either immediate or remote. This principle applies also to certain individual diseases of a grave nature, which may in not a few instances be greatly checked, or even entirely cured, by

appropriate treatment. It opens up a wide range of subjects, and in individual cases it often gives us occasion for deep and anxious thought in determining what is best to be done for our patient's interests, while special difficulties may face us as to carrying out a method of treatment which we know is clearly indicated. There are some who, in relation to certain of the conditions to which I allude, are, I think, inclined to be too hasty or even rash in the employment of vigorous and heroic measures; but the general tendency is decidedly in the opposite direction, and one sometimes sees an exasperating "pottering" about cases which really call for very prompt and definite treatment.

Without any comment I can now only mention the chief conditions or diseases to which the preceding remarks refer—namely, fluid effusions in the serous cavities; pneumothorax and its effects or accompaniments; purulent accumulations of any kind, whether empyema, pyopericardium, or either of the several abscesses; excessive secretions and morbid products in the air-tubes or pulmonary vesicles, especially if of a purulent or fetid character, as well as materials formed in phthisical cavities, special care being taken as far as possible not to allow persistent accumulation of these fluids in the bases of the lungs; solid inflammatory products in the lungs, the remains of pneumonia or broncho-pneumonia, which even when very extensive and abundant, and of long standing, may sometimes be got rid of entirely by appropriate treatment, systematically and diligently carried out; syphilitic changes, often markedly benefited by specific remedies; aneurysm, which is in not a few instances remarkably amenable to treatment; cardiac thrombosis; and such exceptional diseases as hydatids or actinomycosis.

6. The treatment of temporary disorders of a more or less serious nature, occurring as complications of various diseases or combinations, whether acute or chronic, presents another aspect of the management of chest cases, which always demands thoughtful consideration, as well as often promptitude of action. Many of these disturbances yield readily to simple measures, such as rest, warmth, posture, and the use of old-fashioned and comparatively harmless remedies, such as "ammonia with ether." The obvious tendency nowadays, however, is to rush off to certain special drugs or methods of treatment, without at all considering the case which has actually to be dealt with, or making any attempt to understand the conditions present. I allude more particularly to the treatment of attacks of spasmodic asthma and angina pectoris. I have no hesitation in affirming that such attacks, or supposed attacks (for the disturbances called by these names are by no means always correctly so designated), are often regarded from too narrow and restricted a standpoint as regards the adoption of measures for their immediate relief, that different cases require to be treated in different ways, and that it is a serious mistake to fly to any one remedy as a routine practice. Further, we must never forget that by the repeated use of these remedies, which are usually powerful and dangerous, we may be doing positive mischief, and especially that we may be laying the foundation for their habitual employment by patients themselves on the slightest provocation, a practice the injurious results of which we so constantly meet with in these days, when all kinds of drugs and preparations in convenient and attractive forms for use can be so easily obtained. At the same time I fully recognise the remarkable effects which can be produced by certain agents which modern experimental pharmacology has provided for us, as well as their essential value in the treatment of the conditions of which I am now speaking, provided they are employed judiciously, and under the direct supervision of a medical man who knows what he is about. Nor must I forget to note here that some of the very active measures to which I have previously alluded may be urgently demanded in cases belonging to the present category, and that they may be immediately instrumental in averting threatened death.

7. The treatment of symptoms opens up most important questions in relation to combined morbid conditions of the chest, and calls for much consideration in a large number of instances. It is impossible for me now, however, to do more than offer a few general remarks on the point. When in an earlier part of this lecture I strongly condemned the mere symptomatic treatment of chest cases, of course I did not mean to imply that they should not receive due attention when required. As a matter of fact, they often need a good deal of consideration, and it is by no means easy to cope with them under many circumstances in which various thoracic changes exist together. But here comes in the essential importance of studying each symptom individually,

in relation to the conditions present, before attempting to influence it. It frequently happens that we then find that little or nothing can be done for a particular symptom which is troubling the patient, and what we have got to do is to enforce the principle to which I have previously referred—namely, that he must learn to accommodate himself to his circumstances. This applies more especially to disturbances of respiration and cardiac action. On the contrary, it may be that there is some state of things within the chest which can at once be recognised as the cause of the disorder, and that treatment directed thereto will immediately relieve the symptom or symptoms thus produced, even when they are of a severe or grave character. To go on pouring in drugs for the relief of urgent dyspnoea and palpitation (so-called), obviously depending upon a large pleural effusion which demands instant removal, is certainly not rational treatment, and yet it is possible even in these enlightened days. Again, it is often not desirable to check a particular symptom, even when this can be done, such as cough, provided it serves some useful purpose, though it may at the same time perhaps be controlled and helped in various ways. One general rule, at any rate, should be followed in dealing with symptoms in combined chest cases, and that is not to give more medicine than is really needed, and to employ simple and harmless remedies as much as possible. I may draw attention to the great advantage to be derived in relation to thoracic symptoms not uncommonly from the adoption of treatment directed to some particular general condition or conditions, especially anæmia, emaciation, and obesity, though I think the last-mentioned is sometimes rather injudiciously attacked. Nor must I overlook the immense relief to be often obtained by getting rid without delay of certain abdominal accumulations which physically interfere with the diaphragm and thoracic contents, as well as of extensive subcutaneous dropsy. The beneficial effects which thus follow tapping for ascites, or relieving anasarca by operative measures of different kinds, have in my experience of a good many cases been most remarkable.

8. I now come to my last point bearing upon the treatment of combined chest cases, and that is to say a few words about special therapeutic methods. I need scarcely remind you that we are living in an age when, to say the least, there is no great respect paid to traditional therapeutics; and when active and energetic workers are on all hands trying to discover new systems, methods, or even remedies, which will enable us to cope more effectually and successfully with disease in its varied and complex forms. It behoves us, however, as a profession, to be somewhat cautious in our so-called "progress," and not to be too eager to adopt and practise supposed "cures," which a little consideration may show to have really no rational foundation. Such caution is especially necessary in relation to the treatment of diseases of the chest, and a comparatively recent experience gave us all round a lesson which it is to be hoped will not soon be forgotten.

The more prominent special methods of treatment at present in vogue in relation to chest affections may be summed up as follows: 1. Antiseptic treatment, practised in various ways, including intra-laryngeal injections, a method recently brought prominently before the profession by Dr. Colin Campbell. The use of antiseptics may unquestionably be of the greatest value in many combined chest cases, and not merely in those of a phthisical nature. 2. Hypodermic injections of different kinds, which may be rational enough in connexion with certain exceptional conditions, but on the whole, as at present recommended and carried out, rather indicate a want of any actual clinical or even pathological knowledge of the grave diseases with which they profess to deal, and sometimes border on the absurd. 3. Climatic treatment, to which is added not uncommonly some particular "cure." About this treatment—which, of course, is the essential requirement in a large number of instances—I will only say that I find that the "resident doctors" in climatic "health resorts" do not at all like a very advanced or complicated chest case of any kind to deal with, but almost invariably, and for obvious reasons, give their opinion that their particular climate will not be suitable for the patient, and that he had better go elsewhere or stay at home. 4. The use of "respiratory gymnastics," often of the greatest service for various purposes when properly carried out. 5. Methods connected with the employment of "condensed or rarified air," especially for emphysematous cases. 6. Treatment directed to the

nasal cavities and the throat, which in appropriate cases is of unquestionable advantage. 7. Mechanical or physical methods practised in the treatment of cardiac affections, such as massage, graduated mountain climbing, cycling, or special exercises. With regard to these methods, no doubt they are most beneficial in suitable cases, as I can testify, but each one requires very careful consideration before it is treated in any such way.

The preceding remarks have been intended merely to bring to your remembrance, without attempting to discuss them, certain methods of treatment, one or other of which might appropriately be called for in the management of more or less complicated chest conditions. Their individual application must be left to the matured judgment, practical experience, enlightened common sense, and honesty of purpose of each member of the profession to which we have the privilege and honour to belong.

And now, Mr. President and gentlemen, my task is ended. I am but too conscious of the imperfect manner in which it has been performed. One of the greatest and most trying problems which the medical profession has to face at the present day is how to diminish by preventive measures the enormous number of cases of chest disease which overwhelm us on all sides, and how most effectually to cope with these diseases, in their many forms and combinations, so as to restore health, to prolong life, or to lessen human suffering, according to the circumstances and conditions with which we have to deal. I can honestly say that my object in these lectures has been to contribute something, however insignificant, to the attainment of these ends. Increasing experience has made me feel more and more strongly that before we can succeed in our aims in anything like a satisfactory degree we must not be content with a general, and often vague or theoretical, conception of the maladies against which we have to contend, or of their treatment; and I venture further to suggest, with all deference and respect, that we cannot consent to be guided in this matter solely by the teaching of modern experimental pathology and pharmacology. We are bound to realise things as they actually exist in living patients; and it is from this point of view that I have thought it might be of some positive advantage to bring the combinations of morbid conditions of the chest prominently before the profession, at the same time trying to arrange them under some kind of order, to take a comprehensive survey of their clinical investigation, and to glance at the more important principles bearing upon their practical management. On some points I have felt it my duty to speak out with no uncertain sound, but I trust that I have said nothing which can justly give offence to anyone. It now only remains for me most cordially to thank the Council of the Medical Society of London for the great honour they conferred upon me in electing me Lettsomian Lecturer, and to express my deep obligation to you, Mr. President, and to those other gentlemen who have sustained me by their presence and have so patiently listened to my tedious discourses.

NEUROLOGICAL FRAGMENTS.

By J. HUGHLINGS JACKSON, M.D. ST. AND., F.R.S.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND
EPILEPTIC; CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

(Continued from p. 396.)

NO. XV.

SUPERIOR AND SUBORDINATE CENTRES OF THE LOWEST LEVEL.

IN a future note I shall attempt an analysis of a sub-malady of tabes, the Laryngeal Crisis. As a preliminary to doing so, and for other reasons, I will speak further on the evolutionary constitution of the Lowest Level. There are, I submit, in this level, centres of higher rank than those of what I called (No. XIV.) the homologous series (anterior and posterior horns and motor and sensory nuclei of cranial nerves); these centres of higher rank I name Superior Centres of the Level. Certainly the respiratory centre of physiologists (medulla region of the level), to take that case, is not homologous with an anterior horn; it is a superior centre of the lowest level; it represents the respiratory apparatus, or, as I prefer to say, Thoracic Cage (musculature of the larynx, diaphragm, and chest-walls), not directly,

but indirectly; that is, it represents different parts of the thoracic cage by *intermediation* of different motor centres of the homologous series, those which I name, from the parts of the cage they supply, laryngeal, phrenic, and costal centres; these three are motor centres (of the homologous series) subordinate to the medulla respiratory centre. Properly speaking, the respiratory centre *represents* the muscles of the thoracic cage. (Further on in this note I shall make a distinction between different parts of what I call subordinate centres.)

The respiratory centre and its three subordinate centres, with their interconnecting fibres (companion sensory centres and sensory fibres understood) are intrinsic elements of the lowest level. Fibres connecting the three subordinate motor centres with the musculatures of different parts of the thoracic cage, are extrinsic elements of the level, fibres extrinsic downwards. There are fibres connecting the respiratory centre with higher levels; they also are extrinsic of the level, extrinsic upwards. These and certain other fibres differently extrinsic upwards will be spoken of again after a short preliminary.

I prefer the term "thoracic cage" to that of "respiratory apparatus" because there are other than respiratory services of the so-called respiratory apparatus—a question begging epithet. There is not only an organic service ("menial work") of the cage (respiration proper), but it is engaged in non-respiratory, animal services. When a "man draws in his breath" when told to do so (so-called "deep inspiration"), or when he fixes the cage in a high, so-called "inspiratory" attitude whilst lifting a heavy weight, there is a non-respiratory, an animal, service of the cage—one of cerebral (highest level) initiation. I submit that in these animal services there is engagement of motor fibres (of the pyramidal tract) from the highest, through the middle, level; and that in their further course these fibres, evading the medulla respiratory centre, pass direct to the laryngeal, phrenic and costal centres of the lowest level.¹ It must be borne in mind that the motion of the cage when a man draws in his breath when told (so-called "deep inspiration") is of a different kind, obviously in the adult male, from that in ordinary breathing (respiration proper). When an adult male² breathes (respiration proper) the motion of the cage is diaphragmatic first and most, there being a sequent slighter costal motion. But when he draws in his breath when told to do so, the diaphragm acts little, there may be recession of the epigastrium; the chief motion is costal. The latter, an animal duty, is a "voluntary movement," and, as the word "voluntary" implies, is one

¹ I almost ignore all sensory and certain inhibitory elements of the respiratory nervous system of the lowest level in the above exposition; they, especially vagal fibres, including, of course, fibres of the superior laryngeal nerve, are to be tacitly taken into account.

² Marekwald (*The Movements of Respiration*, translated by Mr. Thomas Haig, p. 120) thinks it probable that fibres of the phrenic nerves carry stimulations direct from a motor centre of the surface of the brain, in their passage downwards evading the (medulla) respiratory centres. It may be that these fibres come from cerebral (higher level) *true respiratory* centres, direct to what I call subordinate centres of the lowest level. We must be very careful how we draw clinical inferences from Marekwald's statement, supposing it to be, as he thinks, probable. In some cases of death in coma (cerebral lesion) the respiration is costal and not at all diaphragmatic. (Breathing becomes more costal in anybody when he is excited or when his respiration is rendered difficult by disease.) In the case of coma alluded to the epigastrium may sink whilst the chest rises in inspiration. Such a condition may be, and I believe has been, taken for paralysis of the diaphragm as a direct consequence of the cerebral lesion. And I believe that this condition in dying in some cases of peripheral neuritis has been supposed to indicate paralysis of the diaphragm from lesion of the phrenic nerves. Another explanation of the condition is possible. It may be owing, I submit, to increased volume of the lungs (posterior congestion and anterior "vicarious emphysema") whereby the diaphragm is pushed down. (Compare breathing in certain cases of true emphysema [*volumen pulmonum auctum*] in which there is recession of the epigastrium in inspiration.) Here is, however, I admit, a difficult question, for in some cases of coma from cerebral lesions, even in women, the chest sinks whilst the abdomen rises in inspiration. I have watched the respiratory motions in but few cases of the coma of chloroform, both in men and women; in two or three cases I observed the chest sank whilst the abdomen rose in inspiration. It may be that chloroform poisons the costal centres (lateral horns?) before it poisons the phrenic centres of the lowest level.

³ In the text I speak of the two uses, organic and animal, of the thoracic cage in adult males. Walshe (*Diseases of the Lungs*, fourth edition, p. 36) wrote: "The adult male seems to the eye to breathe with the abdomen and the lower ribs, from about the tenth to the sixth; the adult female with the upper third of the chest alone." So much for respiration proper. Now as to "forced breathing" (voluntary expansion of the cage, as I call it). Walshe writes (op. cit.): "..... The sexual differences disappear in forced breathing; in both sexes the pectoral movement is, out of all proportion, greater than the abdominal, and even in the male the expansile action, if abrupt, commences superiorly."

of cerebral (as I should put it, highest level) initiation; I shall call it "voluntary expansion" of the cage (costal part). The former is a lowest level movement, one initiated by a superior, the respiratory, centre of that lowest level; I shall continue to speak of it as inspiration proper.

I have more to say on the nervous mechanism of the "voluntary," non-respiratory, motion of expanding the cage when told. A further speculation is that the respiratory, medulla, centre in that and other animal services of the cage is inhibited by fibres from the highest level; I suppose that it is so strongly inhibited in such an animal duty as that of lifting a heavy weight, that respiration proper is stopped in order that the laryngeal, phrenic, and costal centres—the respiratory centre ceasing to act on them—may directly serve the highest level. It is not, to speak roughly, that the highest level succeeds in overpowering the influence of the respiratory centre on the three centres mentioned, but that the respiratory centre is compelled to surrender them to the sole activity of the highest level. A man lifting a heavy weight cannot keep his cage fixed for long; when the blood becomes too venous, the respiratory centre is so strongly stimulated that it regains its sway over the subordinate centres in spite of the aforesaid cerebral (higher level) inhibition. The two sets of fibres engaged in the animal, non-respiratory, duty of the cage—motor from the highest level direct to the three subordinate centres, and inhibitory from the highest level direct to the superior, respiratory centre,—are those alluded to at the close of the second paragraph of this note; they are fibres of the level extrinsic upwards. I believe that there is another kind, or perhaps I should say, degree, of higher level inhibition of the respiratory centre.

Besides the occasional, and often strong inhibition of the respiratory centre during "voluntary," non-respiratory services of the cage, there is, I suppose, a continuous (I do not mean unvarying) inhibition of it by the higher levels as it serves, by sub-agency of the subordinate centres, in the "menial work" of respiration proper. I will call this the second kind of higher-level inhibition. I think evidence of slight diminution of the second kind of higher level inhibitory influence upon the medulla respiratory centre is supplied by some cases of hemiplegia, right and left, from lesion in one half of the brain (internal capsule). These cases illustrate also what has been said on the difference of the two, the "voluntary" and the respiratory, services of the cage.

In some cases of hemiplegia, recent and old—I will suppose left is illustration—the motion of the left upper chest is, in a very slight degree, of greater amplitude in inspiration proper than that of the right, whilst the motion of the left upper chest is in a very slight degree of less amplitude than that of the right when the patient expands his cage when told ("voluntary movement"). I will now consider the implications of these differences.

What I have so far spoken of as the respiratory centre is really double, in two halves; there are twin medulla respiratory centres. Applying the principle of Broadbent's hypothesis, on representation of bilaterally acting parts of the two sides of the body in each half of the brain, to the cases of, say, left hemiplegia now under remark, we could only expect there to be very slightly greater amplitude of inspiration on the left side consequent on loss of inhibition from the right half of the brain on but one, the left, of the twin, cross-connected, respiratory centres; and still having regard to Broadbent's hypothesis, we could only expect there to be very slight diminution of motion of the left side of the cage from loss of "voluntary" influence from a lesion in the right half of the brain.

Recently I have, with the assistance of Dr. W. H. Stoddart, investigated twenty-eight cases of old hemiplegia in this regard. Most of the observations were made by Dr. Stoddart. In seven cases of left, and twelve of right hemiplegia, the upper chest on the paralysed side moved very slightly more than on the non-paralysed side in inspiration proper, and in "voluntary" expansion, moved less on the paralysed side, than on the non-paralysed side. The wording of the foregoing implies that there appear to be exceptions to what I believe is the rule; there is the obvious complication of old thoracic disease in some cases.

What has been said on the respiratory motion of the cage in some cases of hemiplegia bears on Cheyne-Stokes respiration. In very grave cerebral lesions with Cheyne-Stokes respiration, the continuous which I called the second kind of higher level inhibition by both halves of the brain is probably taken off both respiratory centres. This double taking off

will, again having regard to the principle of Broadbent's hypothesis, be far more than the double of taking off, as in the cases of hemiplegia mentioned in the foregoing, of inhibition from one of the two respiratory centres by lesion of one, the opposite, half of the brain. The twin respiratory centres bereft of higher level inhibitory influence will still be under vagal inhibitory influence, except perhaps in cases where the lungs have become gorged.⁴ The respiratory centres in cases of Cheyne-Stokes' respiration due to a grave cerebral lesion will be left more than is normal to their own inherent automatism and will presumably be more susceptible to the state of the blood, and perhaps to the influence of the vagi. There seems to me to be in Cheyne-Stokes respiration from cerebral lesions something analogous to hippus. When in patients subject to this ocular peculiarity, light goes into the eye it stimulates the retina; therefrom, indirectly of course, the pupil contracts; the pupil being contracted, less light enters to stimulate the retina and the pupil dilates; and so on again and again. In the case of Cheyne-Stokes respiration I am considering the supposition is that higher level inhibition is taken off both medulla respiratory centres; whereupon, respiration proper being greater, apnoea occurs and the respiratory movements cease. At length from this cessation the blood becomes super-venous, and thus the respiratory centres are stimulated and there ensues a number of respiratory movements of gradually increasing amplitude; wherefrom, the super-venosity again ceasing, the respirations diminish gradually in number and amplitude and there is again the pause; or once more from this cessation of respiratory movements super-venosity occurs, and then once more there is stimulation of the respiratory centres, and another series of respiratory movements.

For a clearer understanding of the differences of the two kinds of motion, animal and organic, of the thoracic cage, I must speak more definitely than I did by using the morphological terms anterior horns and nuclei of motor cranial nerves, or by using the term subordinate centres. It is not likely that the elements of what I called the subordinate centres which are acted on by higher levels in the "voluntary" (animal) service of expanding the cage when told and during "effort," are the same elements as those which are acted on by the respiratory (medulla) centre in the organic service of the cage (respiration proper). The former elements are probably those of the cell column, whilst the latter (for the costal centres) are, considering Gaskell's researches, probably the lateral horns.⁵ So then, amending former statements, we say that during "voluntary" expansion of the cage, the respiratory centre, being inhibited, ceases to act on the lateral horns for the direct supply of the muscles of the cage and the higher levels then act on the cell column, or some part of it, also for the direct supply of the muscles of the cage. If this be so, we see the importance of distinguishing between action of muscles and movements; the intercostal muscles serve in two different movements.

More generally and with regard to the organs of the digestive, circulatory, and respiratory⁶ systems, the supposition is that they are in adult man efficiently, I do not say solely, represented by the lowest level, as they do the "menial work" (organic service) of digesting food, circulating blood, and aerating blood. I imagine that there are superior and subordinate centres of the lowest level for the "menial work" of each of these systems, but I refrain from

⁴ McKendrick (Text-book of Physiology, "Special Physiology," p. 356) writes: "Division of the vagi at once causes periodic breathing to disappear [in animals when the medulla has been divided above the respiratory centres], and in its place there are irregular respiratory spasms. It is clear, therefore, that periodic breathing occurs when the upper nervous tracts are inactive and when in these circumstances the vagi convey impressions to the respiratory centre. Hence it is that the Cheyne-Stokes phenomenon appears when the higher nervous centres are totally or partially inactive, or, at all events, when the upper brain tracts are not conveying impressions downwards."

⁵ Since I wrote the above I have met with what I think is clinical confirmation of the hypothesis as to the difference between the two (the "voluntary" and the organic) services of the thoracic cage, or rather of the costal part of it. I refer to the case mentioned in No. 12, THE LANCET, Dec. 22nd, 1894, a case in which, with loss of the respiratory movement of the intercostal muscles, good "voluntary" movement by the same muscles remained possible.

⁶ I neglect the animal heat system in this note. There is, I think, nothing absurd in suggesting, as I now do, that at least some of those thermic centres, which are supposed to exist in the brain, may be centres of the lowest level; for lowest level is an anatomico-physiological, not a morphological, expression. I am not speaking of the sensation heat; that, like all other sensations, no doubt arises concomitantly with activities of the highest cerebral centres. Thermogenesis is a part of physiological physics. It does not follow that any cerebral centres any way concerned with animal heat, the thing physical, are centres during the activities of which the sensation heat arises.

giving details of the speculation on this matter in these cases. One general hypothesis is that as the organs of the three systems do that "menial work," they are very little positively (that is motorily), but much negatively (that is inhibitorily), represented (properly re-represented) in the higher levels; I speak, in this regard, of adult man.

With regard to the positive representation of the respiratory apparatus (which I call the thoracic cage) in the higher levels (Rolandic cortex), Horsley and Semon have written much to the same effect with regard to its organic ("menial") and animal services, or those two different services of a part of it (larynx). Some of the results of their experiments are, I think, in harmony with certain doctrines to be presently adverted to put forward by Herbert Spencer. Horsley and Semon write,⁷ speaking of the vocal cords: "We have seen that the first of these functions, phonatory adduction [what Semon call 'purposive' or 'volitional'] is represented most completely in the cortex the higher we ascend in the animal scale, and the more completely as the cortex is developed in the life of the individual, i.e., by age, while, *pari passu*, the function of respiration, although present in a minor degree as evidenced by acceleration, is least represented where phonation is most completely developed. *Respiration is represented in the higher animals only as acceleration and that above and rather in front of the focus of phonation.*" (These words are not in italics in the original.) Semon and Horsley⁸ write: "Of all animals experimented on by us, the cat appears to possess the greatest development, the monkey the least, of respiratory representation in the cortex, since in the former animal alone have we found an actual centre for genuine abduction [of the vocal cords] to exist, close to the border of the olfactory (rhinal) sulcus. A similar preponderance of cortical representation of respiration, we have found in young animals of different species."

Now as to negative representation (inhibition) of the respiratory centres by the higher levels. I cannot say that there is experimental evidence to show that, as the higher levels from lower to higher mammals, and from young to grown-up animals, come to have less to do with the direction of organic operations these levels come to have more suspensive, inhibitory, power over those operations. I, however, submit the following extract from a very valuable paper⁹ by W. G. Spencer, *The Effect produced upon Respiration by Faradic Excitation of the Cerebrum in the Monkey, Dog, Cat and Rabbit*. Mr. W. G. Spencer writes, "*An Increased Action of the Respiration in the Monkey*": "I have been forced to distinguish the monkey from the rabbit, cat and dog, because in it an increased action of the respiration is so much less marked. There appears to be no fundamental difference, for I have obtained the same reactions 'acceleration,' 'over-inspiratory clonus' and 'over-inspiratory tonus,' at the points corresponding to those of the other animals, but only to a much smaller degree. The monkey reacts like the other three species do when [they are] very exhausted. I have not yet succeeded in artificially producing a greater excitability of the monkey's brain so as to obtain marked increased action of the respiration. The result of such attempts has been to excite irregularity of the rhythm and general convulsions. This lessened representation of the other phenomena, or the relatively greater sensitiveness to the effects of anaesthesia on the part of the monkey, allows slowing and arrest to be obtained all the more readily, and the localisation of the points of representation to be more easily recognised, since the effect is not so liable to be complicated by a simultaneous calling forth of increased action." (No italics in original.)

The wording of the foregoing (I mean what I have written in this note on the representation of the digestive, circulatory and respiratory systems) implies—at any rate it is meant to imply—that the organs of the three systems are very much positively represented in the highest level as they are concerned in non-menial work—that they are very much represented in the anatomical substrata of consciousness. I have already spoken of this with regard to the thoracic cage, have implied that it is largely represented positively in the highest level for "voluntary," animal, duties. Plainly the cage is engaged during emotions. I submit that its unusual engagement during strong emotion, the physical process being cerebrally initiated, is not a true respiratory service; at any rate the

"menial work" of the cage, respiration proper, goes on badly so far as emotion is concerned. To take an extreme case, artificially limiting the illustration; it is scarcely likely that the heart is much, if at all, positively represented in the highest centres as it does the "menial work" of circulating the blood. Yet, as popular phrases ("hard-hearted," "kind-hearted," &c.) imply, it is no doubt represented for other purposes (re-represented) in the highest cerebral centres; obviously it must be represented in the anatomical substrata of emotions; but during great emotion, plainly during great fear, the heart serves badly in "the menial work" of circulating the blood, that is in its character as a blood-pump.

An hypothesis implied by what has been said in this note is that the lowest level is, for organic duties ("menial work"), by itself very efficient, and that it is for those duties considerably independent of the motor, directive, influence of the higher levels, although much under their negative (inhibitory) influence. Another general doctrine is that the centres of the lowest level which serve in organic ("industrial") duties can be compelled by higher levels to suspend those duties in order that the higher levels may act on animal centres of the level in "voluntary" operations. All this seems to me to be but an application of Herbert Spencer's doctrines on analogies between an individual organism and a social organism, as the use in a part of the foregoing of the word "industrial" is meant to signify.

I suppose that there are other superior centres of the lowest level, some in regions of it lower than the medulla region; for example, there are probably superior centres for the bladder and rectum in the lumbar region of the level, with centres subordinate to them in its sacral region.

I imagine that the corpora quadrigemina are superior centres of the lowest level; that they serve not to co-ordinate the retinae by the optic nerves and tracts with ocular muscles for the estimation of distance, at least of objects out of reach (that is as the ocular movements symbolise so much locomotion), and not as they co-ordinate locomotor movements, but that they serve in co-ordinating both these co-ordinations; or to use a Spencerian term, that they, like the respiratory centres, are centres of Compound Co-ordination.

MYXCEDEMA AND ITS RELATION TO GRAVES' DISEASE.¹

By P. CAMPBELL GOWAN, L.R.C.P. LOND.,
M.R.C.S. ENG., L.S.A.

THE disease we are about to consider is comparatively rare. Personally I have had the good fortune to recognise six cases in the last ten years, or an average of three-fifths of a case a year, a ratio which you will admit is not large. Prior to 1870 the disease was practically unrecognised in adults, while in children it was called "sporadic" or "endemic" cretinism, and was looked upon simply as a peculiar form of idiocy. In its so-called endemic form it was known to exist in many Alpine villages, and I have a vivid recollection of the ugly little imps I met with in a certain village when on a walking tour in the Swiss Alps in 1865.

Historical summary.—In 1873 Sir W. Gull read a paper before the Clinical Society of London on a Cretinoid State Supervening in Adult Life in Women. In 1877 Dr. Ord presented a communication to the Medical and Chirurgical Society on Myxcedema. These two papers detailed cases and described diseases which were beyond doubt identical. To Dr. Ord belongs the credit of having discovered that the essential feature of the disease was a mucin-yielding cedema, and that the thyroid gland was in all cases either atrophied or cirrhotic. In 1881 Charcot described the result of his clinical observations, and named the disease cachexia pachydermique. In 1882 M. Reverdin drew attention to the symptoms following extirpation of the thyroid gland, and resembling those of myxcedema. In April, 1883, Professor Kocher read a paper before a congress of German surgeons, describing the symptoms he found to follow the total extirpation of the thyroid gland, and which he described under the term of "cachexia strumipriva." Dr. Felix Semon, in November, 1883, pointed out the resemblance of the symptoms described by Kocher to those of myxcedema

⁷ Transactions of the Philosophical Society, 1890, B., p. 209.

¹ A paper read before the West Herts Medical Society.

observed in England; and in December, 1883, a committee of the Clinical Society of London was appointed to investigate the phenomena of the disease. From their report, published in 1888, the above facts have been culled. Soon after the appointment of the committee, Mr. Victor Horsley commenced a series of experiments on monkeys, and succeeded in demonstrating that loss of function of the thyroid gland produced all the symptoms known as myxœdema and cachexia strumipriva.

Characteristic symptoms.—1. The most obvious of these is a disfiguring œdema of general distribution over the body, and peculiar in that it does not pit on pressure. 2. There are slowness and thickness of speech, a tottering gait, a peculiar pallor of the skin, and fetor of the breath. 3. To the touch the skin feels cold, hard, and leathery—altogether unlike that of the normal surface. 4. The hair becomes dry, fluff, and scanty almost to baldness; this applies to the pubes and other parts, as well as to the scalp. 5. The patient, whose temperature is generally subnormal, always feels cold, and will gravitate to a fire in the hottest weather. 6. The bulk and weight are always increased, often to a great extent. 7. Though the specific gravity of the urine is frequently low there is rarely any albumen present, except in those cases in which it is a symptom of concurrent disease. 8. The thyroid gland is small and hard, or not to be felt. 9. Histologically the wasted gland is found to consist of a dense fibrous stroma, with scarce a trace of normal gland tissue left. To my mind, however, the interest in this disease does not centre alone in its peculiar features, but involves the broader consideration of the relation which it bears to another equally uncommon disease—viz., Graves' disease, or exophthalmic goitre. The two following cases will illustrate this point.

CASE 1.—This patient was at one time in my service as nurse to my children. When she was thirty-six years of age she noticed a swelling of the thyroid gland. She had previously suffered from a feeling of fullness in the throat, accompanied by palpitation and proptosis. For these symptoms she was under treatment for two years, at the end of which time they disappeared. She, however, never felt well, and very soon fell into a state of health which was worse than the former. She noticed that her tongue became too large for her mouth, which made her speech slow and indistinct, also that she had always a bad taste in her mouth in the morning. Her urine became scanty and pale, and her periods, which formerly recurred at intervals of three weeks, were often absent for six weeks, and the loss was much diminished. Her hair became fluff and fell out. Her gait became so uncertain that she had to crawl upstairs on her hands and knees. Sensation was impaired, the extremities were numb, and she was oppressed by a feeling of weight. The skin felt dry and leathery, whereas it had formerly been unduly moist. She slept badly and was always cold, and during the winter of 1891-92 she suffered so much from this cause that she could not go out, but sat shivering over the fire all day. Her symptoms were attributed at a London hospital to myxœdema, and she was treated by tonics and diuretics. Oddly enough, she recovered to such an extent as to be able to resume her household duties.

In the second case the connexion between Graves' disease and myxœdema was so obvious that I was led to a closer study of their pathology and to the conclusion that their relation in this instance was by no means accidental. That some such relation should exist seemed to me as logical a sequence as that atrophy should follow upon congestion and cirrhosis of the liver. As in the liver, so in the thyroid, chronic hyperæmia leads to the formation of plastic fibrous tissue, which, if the patient lives long enough, shrinks, crushing and destroying the delicate cells contained in its meshes, until in the end he is left with a more or less useless mass of fibrous tissue in the place of an active gland.

CASE 2.—I first saw this patient, then aged eighteen and a half years, at the end of 1889. I found her the subject of marked Graves' disease. I subsequently learned that she had "gone the rounds of the consultants," both regular and irregular, and had tried everything from arsenic to "blue electricity!" (Mettel.) She gave the following history. At ten years of age she "had a shock" from falling into a pond. Shortly afterwards she had a severe fright, owing to her having accidentally set fire to some drapery. From this date her health became impaired and she suffered from palpitation, fullness of the throat, and painful prominence of the eyeballs. A year later she was in a carriage accident and became worse. Early in 1890 she contracted measles and her

temperature went up to 105° F. The attack was very severe, and the pigmentation left by the rash lasted for some months. From the date of her convalescence from measles the symptoms of Graves' disease became modified. In the intervals of my attendances I saw her frequently as a friend, and she was under my observation from first to last—nearly three years. At the end of 1891 I was asked to examine her carefully, and to give a definite opinion as to her condition, her symptoms having gradually undergone a complete change. As a result of my examination I came to the conclusion that she was suffering from myxœdema—a fact which I had suspected some months previously. Owing to the gravity of her condition I took her to Dr. Ord, who agreed that the case was one of myxœdema in a very early stage of the disease. The notes taken of the case are too copious to condense within the limits of this paper. They, however, form the basis of my remarks in the following commentary. Briefly, her symptoms were those of a disease in every way the opposite to that for which she first came under my care. In fact, she had passed from Graves' disease to myxœdema—from a condition of general exaltation with thyroid hypertrophy to one of depression with atrophy of that gland—a striking and unique illustration of the deterioration of an over-stimulated organism. Those who have carefully watched a case of Graves' disease must have observed that the condition of the whole vascular system is one of congestion. Every organ is over-full of blood, and the heart works like an express engine in keeping up the high pressure. The arterial tension is, however, not so great as one would expect it to be, and the force of the cardiac contractions is less marked in the radials than in the carotids. This we may conceive to be due to two causes: (1) vaso-motor paresis, which allows of the rapid absorption of increased force; and (2) a ventricular systole of unequal tone, forcible, and quick at the commencement of the contraction, but rapidly becoming weaker—in fact, the jerky action of an irritated and jaded muscle. From this it follows that the vessels and organs nearest the heart would feel the effect of the increased force sooner than the distal vessels, just as in certain cases of valvular disease only one beat in two is felt at the wrist, while every pulsation can be counted in the carotids. Those organs, consequently, which show the most marked evidence of excessive blood-supply are the thyroid, the eyes, and the brain. In the thyroid it can be felt, in the eyes it can be seen, and in the brain it is evidenced by the excitability, the passion, and the rapid cerebration and speech. (It is difficult to understand why it was ever considered necessary to seek the aid of the insignificant muscular fibres of the orbital membrane to explain the proptosis when the abnormal tension of the eyeball, and the congested scleral and episcleral vessels only too plainly indicate the cause.) The frequent pulse necessitates an increased rate of respiration and the temperature is high, nearly always above normal. The skin is hot and moist and the mouth is full of saliva, evidence of glandular activity the result of hyperæmia. Such briefly are some of the salient features of Graves' disease. Now in myxœdema the tables are completely turned. The pulse becomes slow and feeble; the thyroid becomes small and hard and is barely perceptible. The eyeballs recede to a certain extent, and the palpebral skin is thrown into heavy folds. The integument of the body becomes cold, dry, and leathery, and the extremities feel numb. The mouth, too, becomes dry and the saliva sticky. Cerebration is slow and speech sluggish. The appetite, previously voracious, is lost; constipation follows and the pill which once acted copiously now barely takes effect and soon has to be increased in strength. The temperature falls (even below 95° F. in the morning) and rarely, except during the catamenial period, reaches the normal level. The heart sounds are weak and soft and the impulse is lost, though the basic murmur persists. The patient is no longer restlessly energetic, but becomes alternately peevish and apathetic and crouches over the fire in the vain endeavour to keep warm. The catamenia, previously regular and often profuse, become scanty and are absent for months; the hair becomes fluff, dry, and brittle, and falls out "by the handful." Such is the contrast between the two diseases as exemplified in this case, and I venture to believe that the relation which here evidently existed between them will be found to be more common the more the subject is studied and the more carefully the previous history of each case of myxœdema is investigated.

As to the origin of Graves' disease it is barely profitable to speculate. That it is due to a lesion of the vaso-motor area in the bulb is very probable, and that the thyroid

enlargement is merely a consequence is almost certain. The changes in the cervical ganglia of the sympathetic are also probably secondary. What it is that produces the central lesion still remains in the region of hypothesis. Someone may some day discover a bacillus. At present severe mental strain or nerve shock is credited with its production. As bearing upon the title of this paper and the object I have had in writing it, I would point to the significant fact that the ratio of males to females affected is almost identical in both Graves' disease and myxœdema—that is, about one to six. Of six cases of myxœdema which I have seen since 1884 three had histories of previous thyroid enlargement and concomitant symptoms. The first two I have just related; of the third I have no notes, and it is consequently valueless. In the remaining cases no history of exophthalmic goitre was obtained. However, from the facts already mentioned and from others which the compass of this paper will not permit me to discuss, from the sequence of events in the two cases detailed, and from the study of the pathology and histology of both diseases, I am led to believe that myxœdema is certainly a possible, and may even be a probable result of an antecedent Graves' disease.

Treatment.—My experience is limited to five of the six cases just alluded to. The first case recovered under tonic and diuretic treatment alone, possibly because some part of the gland escaped destruction and, subsequently becoming hypertrophied, sufficed for the needs of the body. The most recent case is still under treatment with the "extract," and already shows some improvement. In three of the cases the result of the treatment by thyroid extract savours of the miraculous. Snatched from a life of unloveliness and suffering, the patients have been restored to health, beauty, and vigour. Surely their gratitude is due to those members of our profession whose acumen led them to the discovery of a remedy the therapeutic value of which is as yet but very imperfectly gauged, and which has opened up a field of research full of brilliant promise for the future.

Great Stanmore, Middlesex.

CASE OF LARGE POLYPOID GROWTH IN THE UTERUS BECOMING SARCOMATOUS; UTERUS AND GROWTH REMOVED BY COMBINED ABDOMINAL AND VAGINAL HYSTERECTOMY; RECOVERY.

By FRED. BOWREMAN JESSETT, F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

THERE are few cases that come under the notice of a gynaecologist which cause him more anxiety than cases of fibro-myoma of the uterus, and when these tumours become sarcomatous, as they occasionally do, the difficulty in dealing with them is very much increased; in fact, the only hope of eradicating the disease from the system rests on the total removal of the organ with its disease. Such removal is always attended by considerable difficulty. If the uterus is not much enlarged they may be removed per vaginam; but if the growths have attained considerable size this proceeding is impossible, and it becomes necessary to consider what is the best method of removing the organ—whether to remove it through the abdomen by Freund's operation or to adopt Martin's operation of combined vaginal and abdominal operation, and finally, the uterus with its growth being removed, to consider what is the best plan to adopt in dealing with the peritoneum. The following case is one, I think, of very considerable interest and importance in connexion with these questions.

On April, 9th, 1894, I was asked by Mr. J. R. Walker of Hamilton-terrace to see with him a widow fifty-seven years of age. She had three children, the youngest being about thirty years of age. She had enjoyed good health until about three or four years ago, when she had some violent floodings, for which her medical man, at that time, took her to see Dr. Braxton Hicks. She has had a great deal of worry and anxiety. There is no history of cancer in the family. In answer to a letter I wrote to Dr. Braxton Hicks as to her condition when he saw her, he most courteously sent me the following particulars: "About two years ago I saw the patient in question. She had then a sloughing fibroid; the greater portion of the mass came away, but some remained. She gradually

improved in health and got about. I saw her about four months ago. She was then without offensive discharge; there was leucorrhœa, and the uterine tumour was about the size it was when I saw her before. There was nothing then to indicate change of growth or operation." Since then the patient had complained of pain in the back; she could not walk without a good deal of distress. She had had attacks of bleeding and some badly smelling discharge. The jolting of cabs and omnibuses caused her great pain. She had had two attacks of intestinal obstruction, one a very severe attack. By abdominal examination there was discovered to be a well-marked tumour situated somewhat deeply in the pelvis; the parietes were flaccid and admitted of ready examination. The patient was well nourished, although she had lost flesh of late. The tumour appeared to extend somewhat along the left broad ligament. A boss was also felt about the size of a Tangerine orange apparently in the right broad ligament. Per vaginam the os felt healthy; there was no erosion or ulceration. The uterus was readily movable; the tumour appeared to be in the body of the uterus; there was a good deal of thickening of the left broad ligament. A sanious, blood-stained, badly smelling discharge was seen escaping from the os; this discharge was seropurulent in character and caused a good deal of irritation of the labia. The sound passed readily for four inches and a half; slight bleeding followed its introduction. Bi-manually the uterus presented a soft, doughy sensation; it was freely movable excepting on the left side, where it seemed to be slightly held down. The diagnosis arrived at was that there had been a fibroid growth in the uterus; but taking into account the age, the offensive discharge with hæmorrhage, and the fact that it had been growing of late, I was of opinion that we had to deal with a growth of a sarcomatous character and advised early removal, which, after consideration, was agreed to by the patient and her friends. On April 19th, with the assistance of Mr. Walker, Dr. Purcell, and Mr. West, Dr. Dudley Buxton administering the anæsthetic, I performed the following operation. From the size of the tumour it was recognised that considerable difficulty would be experienced in removing the uterus with its growth per vaginam, although I hoped to be able to do so. I was, therefore, prepared to open the abdomen in case such difficulty was experienced, which proved to be the case. For three days preceding the operation the vagina had been syringed out three or four times a day with carbolic lotion, and tampons of wool soaked in the lotion had been kept in the vagina. Before the patient was placed on the table she had an enema composed of two ounces each of beef-tea and brandy. The patient was placed in the lithotomy position and the vagina was well washed out with a 1 in 40 carbolic solution. The os uteri was then seized with vulsellum forceps and readily drawn down to the vulva. The mucous membrane was next divided round the whole circumference of the cervix and the anterior and posterior cul-de-sacs of the peritoneum opened. The uterine arteries were now secured and the uterus freed to a point above the arteries. I next endeavoured to tilt the uterus, both anteriorly and posteriorly, but from its size found it impossible to deliver it. I then discussed the advisability of opening up and dividing the uterus, but as I believed the tumour to be a sarcoma, and there was a risk of soiling the peritoneum extensively if I adopted this procedure, I determined to open the abdomen in the middle line and finish the operation from above. The patient still being retained in the same position, I, standing as before, after shaving the pubes and thoroughly cleansing the skin, made an incision some three inches long in the middle line and seized the fundus of the uterus with vulsellum forceps and readily drew it through the wound; I then found that the left ovary and tube were matted together to a loop of intestine. I detached this and ligatured the broad ligament from above downwards, first on the left and then on the right side, the lowest ligature meeting that which had been passed round the uterine arteries from the vagina. The broad ligaments now being divided between the ligatures and the uterus, the latter was easily lifted out. The abdomen was flushed out with warm water, being allowed to drain out through the vagina. All bleeding being arrested I caught the two flaps of peritoneum with curved pressure forceps through the vagina and drew them down, introduced a glass drainage-tube into the peritoneal cavity, and packed the vagina around the drainage-tube with strips of iodoform gauze. The patient, who was very exhausted, was now returned to bed. She rallied rapidly and in the evening was quite comfortable. The drainage-tube and gauze packing

were removed the next day, as the patient complained of a good deal of pain in the right side. Most of the ligatures were removed at the end of the week. There was a good deal of discharge, and pain was complained of in the right iliac region. On the tenth day there was a sudden rush of pus, which appeared to come from the right side rather high up; after this the temperature, which had been 102° and 103° F., dropped, and the patient was much easier. At the end of a fortnight the discharge had much decreased, and a large slough with some ligatures came away. The patient three weeks after the operation was lifted on to the sofa, and Mr. Walker writes to me that at the present time (Feb. 20th, 1895) she is in good health.

Remarks.—This case is one of interest, I think, from two points of view: one the fact of these large intra-uterine fibro-myomata becoming sarcomatous, and the other from the method in which the operation was performed. Sir John Williams has in his Harveian Lecture drawn attention to the way in which carcinomata occasionally assume a polypoid shape, while the uterine wall at their base may be healthy. These polypi, as Ruge and Veit and John Williams have explained, may break down and disappear, leaving a mass of cancer in the uterine walls. It is fully recognised that fibro-myomata of the uterus do undergo sarcomatous degeneration; thus, as Mr. Plimmer has drawn my attention to, Dr. Sims Woodhead¹ observes that portions of a fibroid tumour (of the uterus) undergo sarcomatous degeneration. Mr. Alban Doran² gives an account of a case of a fibroid becoming sarcomatous. Dr. Finlay³ showed a case at the Pathological Society of a large fibroid which had become sarcomatous, the patient dying from secondary deposits in other organs. Numerous other instances have been recorded by Playfair, Cornil, and Ranvier, Pozzi, and others; but in none of these do they, I think, describe just the condition which existed in this case—viz., an intra-uterine fibro-myoma assuming a polypoid form, being connected with the fundus of the uterus by a narrow pedicle, and then becoming sarcomatous. Mr. Plimmer has kindly furnished me with the following pathological report of the specimen. He says: "The tumour consists of non-striated muscular tissue and sarcomatous material in varying proportions. In the hard parts it is almost entirely of the ordinary 'uterine fibroid' structure, but in all but the very hardest parts there is some sarcomatous material with it. The softer parts are almost entirely sarcomatous, with bands of connective tissue, which are rich in fusiform cells with prolongations of various length between; these bands are large collections of round cells with well-marked nuclei closely packed together. In the superficial parts are bundles of fibrous and unstriated muscular tissue. The blood-supply is rich, and there are around the vessels some spots of hemorrhage. No mucous membrane or glands found." The operation was conducted much in the same way as described by Martin (Berlin), although I have never seen this surgeon operate. The advantages I think are obvious: first, from the position the patient is placed in, the abdominal parietes are made quite lax, so that it is easier to withdraw a tumour through the abdominal wound; secondly, the surgeon has complete control of the vaginal and abdominal openings, and so is enabled much more accurately to ligature the broad ligament, and the peritoneum and vagina are more readily and thoroughly washed out and all clots removed; the final steps of the operation differed from Martin's method in that he laces the peritoneum across through the abdominal wound, thus closing the peritoneal sac. I prefer, as I have mentioned on many former occasions, to draw the two flaps of peritoneum down into the vagina and packing around these strips of iodoform gauze, passing for the first twenty-four hours a glass drainage-tube into the peritoneum. The specimen consisted of a large polypoid growth, lobulated, in some parts very hard, at others soft and cystic. It is attached to the fundus of the uterus by a narrow pedicle. The uterine walls are somewhat soft and thinned. The cervix and os appear to be quite healthy.

A CONTRIBUTION TO THE PATHOLOGY OF CHLOROFORM SYNCOPE.

By ALEXANDER HAIG, M.D. OXON., F.R.C.P. LOND., &c.,
PHYSICIAN TO THE METROPOLITAN HOSPITAL AND TO THE ROYAL
HOSPITAL FOR CHILDREN AND WOMEN.

THE extremely interesting paper by Mr. A. Wilson¹ and the notes and papers which have followed it have brought prominently before my mind the argument as to the causation of chloroform syncope which I have elsewhere given.² My argument is that syncope following the administration of chloroform has an identical causation with those more common conditions of syncope seen in connexion with high and rising blood pressure, and that in all cases it is the high and rising blood pressure which overpowers the heart and produces the syncope. It is generally acknowledged that the effect of chloroform inhalation is to lower the blood pressure, and it follows from this that when the chloroform has been stopped and its effects are passing off there will be a rise of blood pressure. Now I have good reason to believe that this rise of blood pressure is a danger to the heart, and that this danger is increased the greater and more sudden the rise and the weaker the heart or the more imperfect its nutrition. Further, the very interesting experiments and observations of Dr. R. Kirk³ show that a similar irregularity of the heart and tendency to syncope is met with in animals after the last drop of chloroform has left the blood; and he has further pointed out that in the human subject these troubles often occur during a break in the administration or soon after it has been discontinued, and this is a point which several of the cases recently discussed in THE LANCET illustrate in a remarkable way. Thus in Mr. Wilson's Cases 1 and 2 we have, as he truly says, all the signs of primary failure of the circulation, and in his Case 6 we have this occurring as the patient is coming round and is sufficiently conscious to give a cry of pain; but whether in Cases 1 and 2 the syncope came on during slight breaks in the administration of the chloroform, as contended by Dr. Kirk, there is not sufficient evidence to show. With regard to Case 6 Mr. Wilson remarks that the syncope was due to the reflex inhibition of the heart by the pain, but that some blame must also be laid upon the semi-anæsthetic condition of the patient at the time, but I shall have to speak of these points again. It is interesting to note also that Mr. Wilson agrees with Dr. Kirk in looking upon a sudden quickening of the pulse as a danger signal.⁴ Dr. Kirk also mentions in the reference just given the case of a patient who died from "the reaction which ensued when he began to breathe fresh air."

Then in THE LANCET of Nov. 24th, 1894, there is the record of a case of syncope under chloroform in which nitrite of amyl averted a fatal result and its effect is said to have been "almost instantaneous." I have elsewhere suggested that this drug acts by reducing the blood pressure and thus freeing the heart from its overpowering effects (for another case in which it was used with success see THE LANCET of March 7th, 1885). And even in the same number of THE LANCET (Nov. 24th, 1894) there is the record of a case in which death ensued, and it is said with regard to the onset of the fatal signs that "the administration of the chloroform had been stopped," and in an annotation on the same case in the next number (p. 1291) further points of great interest are mentioned: (1) that she had taken chloroform with impunity on other occasions; (2) that she had been confined fifteen months previously and had recently lost a child, and was suffering from the depressing effects of grief; (3) that there was slight renal disease (and I note also that one of Mr. Wilson's cases suffered from chronic Bright's disease); and (4) that "before the dentist had touched the patient, although the chloroformist had taken away the chloroform from her face and pronounced her ready for operation, she suddenly became ashy pale, but respiration continued"; here, then, we have exactly the condition described and insisted upon by Dr. Kirk and Mr. Wilson.

Another death under chloroform—in which there was great difficulty in giving the anæsthetic owing to the nose being the point to be operated on, and where the patient, therefore,

³ THE LANCET, Aug. 19th, 1893.

⁴ THE LANCET, June 23rd, 1894.

DR. R. BALLOTA TAYLOR, an English practitioner residing at Santander, Spain, has been recently elected Corresponding Member of the Royal Academy of Medicine of Madrid

came round several times before the fatal event—is recorded in THE LANCET of Aug. 26th, 1893, and similar deaths from too little chloroform or a lull in the administration were discussed in 1892 and 1893.⁵ I have mentioned above Mr. Wilson's opinion that in his Case 6 the syncope was due to the reflex inhibition of the heart by the pain; but it seems to me that a somewhat different relation between cause and effect to that he suggested is possible. Thus I have said, with reference to the effect of high blood pressure on the action of the heart,⁶ that my own heart never falters or flutters except when there is high or rising blood pressure; but there is one condition I ought to have mentioned in which my heart does flutter or falter just as in pulse tracing A⁷ (which shows well-marked high arterial tension), and that is during severe irritation of a sensory nerve. I happen to suffer many things with the dental branches of the fifth nerve, and I have several times noticed that with the most severe paroxysms of pain my heart falters and flutters just as it was doing when the above-mentioned pulse tracing was taken, for these cardiac irregularities, not being habitual with me, are always distinctly felt. Now, in the case of my own heart was this a reflex or was it due to rising blood pressure? If we may consider—and, so far as I know, physiology does not negative the idea—that irritation of a sensory nerve causes a general contraction of arterioles and a rise of blood pressure, the cause was in both cases the same, and my heart fluttered under the dental pain for the same reason that it did so in pulse tracing A, because in both there was high and rising blood pressure. We can now fully appreciate the bearing of Mr. Wilson's Case 6. Here the patient was coming out of the chloroform anaesthesia, and blood pressure was therefore rising; suddenly to this was added severe irritation of the sensory nerves of the knee, causing an acute rise of blood pressure, and it was little wonder that the heart was thus completely overpowered and that syncope at once resulted. And this explanation reminds me again of Marey's observation, which I have elsewhere quoted, that changes in the rate and rhythm of the heart, while often attributed to nervous influences, are in not a few cases really due to pressure changes in the vessels.⁸ If further we may take it, as I have suggested, that excess of uric acid in the blood is the most common and potent cause of high blood pressure, we can easily understand the fatal result in Mr. Wilson's Case 2, with atheromatous arteries and granular kidneys, and in the other case mentioned above where there was slight renal disease, and this patient also had been suffering under the depressing effects of grief, while recent pregnancy and other factors are mentioned. Now I have no hesitation in saying that in one and all of these conditions there would probably be excess of uric acid in the blood, and that they are just the conditions in which I should expect syncope after chloroform to take place. I quite agree with Mr. Wilson that one cause of death after chloroform is syncope, and endorse his valuable suggestion that syncope under other conditions should be studied to illustrate it; and if this is done many will, I believe, be astonished to find how large a number of syncope cases are preceded or accompanied by evidences of high and rising blood pressure, and, if these can also be examined, with excess of uric acid in the urine and blood.

I make these suggestions for what they are worth—for a place beside other hypotheses; but if they are ever proved to be true it is evident that we should soon be in a position to prevent or to avoid all such cases of syncope, and also to say with considerable certainty in what cases and conditions it is dangerous to give chloroform.

⁸ Circulation du Sang, p. 484.

THE annual meeting of the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, was held on Feb. 14th at 34, Craven-street, Charing-cross, Sir Algernon Borthwick presiding. Suitable reference was made to the death of the founder of the hospital, Dr. Arthur Hill Hassell, a portrait of whom has been placed in the large dining hall. During 1894 there were 793 patients, a higher number than in any former year. The income exceeded that for 1893, chiefly in consequence of a gift of £1500 from an anonymous donor.

FURTHER CASES ILLUSTRATING THE RESULTS TO THE EMPLOYÉS OF IMPERFECT VISION TESTING ON RAILWAYS AND IN THE MERCANTILE MARINE.

By W. C. ROCKLIFFE, M.A., M.B. CANTAB.,
OPHTHALMIC SURGEON TO THE HULL ROYAL INFIRMARY.

AS might be expected in a seaport town, I could, if I had time to peruse my notes of the last twenty years, find many cases to substantiate the contention of the deputation of ophthalmic surgeons which recently waited on the Board of Trade, which I take to be "that it is unfair both to the patients themselves as well as the general public that the testing of the acuity of vision and colour sense of railway and marine officials is not undertaken in every case by persons fully versed in ophthalmic knowledge and capable of detecting without doubt either errors of refraction, achromatopsia, or diseases of the eye—more especially the fundus." In support of which statement I quote from cases which have come under my care during the last eighteen months.

CASE 1.—A man aged thirty-eight had since boyhood been to sea and gradually risen to the obtaining of his master's certificate. Three times had his sight been tested, including colours, and each time he passed without difficulty; but on presenting himself as master he was found to be colour-blind and rejected. On examination he selected for green—salmon, grey, and drab; called rose green, and selected blues and purple; and matched bright red with dark brown.

CASE 2.—A young man aged twenty-five years had during the nine years he had been at sea never experienced any difficulty in "picking up lights," and had passed the colour test twice before, but was rejected on passing for master. On examination he selected for green—greys and light brown; for rose, purple and blue; and for red, dark brown.

CASE 3.—This case particularly exemplifies the hardship entailed by inefficient examination. A young man aged twenty-two years had been educated at a public navigation school, been second and first mate, and obtained his master's certificate, but was rejected at the moment his appointed ship was awaiting its captain. Throughout the whole of his life he bore a most exemplary character, and had twice been passed by the same examiner before rejection. His surprise and disbelief in his colour blindness caused him to consult me. On examination he called green green, but selected drab, salmon, and grey; he called rose light green, and selected blues, violet, and emerald green; and he called red red, but selected dark brown and claret.

CASE 4.—A young man aged twenty-three had worked his way through the shops, been engine-cleaner, and afterwards fireman for three years and a half, and was refused his driver's certificate on one of the largest lines in England on the ground of colour blindness. On examination he selected as green—magenta, drab, grey, and buff; and as rose—emerald green, ultramarine, and violet.

I have also within my recollection the case of a fireman who could not see the guard's signal at the end of the train, and yet this man had been for some years with the same company, and it was only when his driver refused to take the whole responsibility during foggy weather that his condition was discovered. Another man had considerable amblyopia with atrophy of the optic nerve; and again, a third, an able-bodied seaman, was refused by his captain, a personal quarrel being assumed as the motive; on examination his vision was found to be $\frac{3}{8}$, and he had high myopia, and yet this man for years had taken his watch on a large passenger steamer.

Remarks.—These cases will, I think, add some little proof to the assertion that not only ought our railway officials and seamen to be examined by competent persons before they commence their career, but also (as the deputation further insisted) from time to time while they are following their various avocations; and doubtless a considerable volume of similar evidence might be obtained from many other ophthalmic surgeons, by which even the Board of Trade might be compelled by public feeling to take such steps as were advocated by the deputation, and, as Mr. Beaumont correctly states, prior to some serious calamity at sea or at home. The deputation could not possibly have been composed of a

more powerful assembly of ophthalmic surgeons. Nevertheless, I feel that they might have considerably strengthened their hands had they solicited from their many *confrères* such evidence as was supplied by Mr. Beaumont in THE LANCET of the 9th inst. The whole matter was somewhat "rushed" at the meeting of the Ophthalmological Society on Jan. 31st, and an influential deputation was promptly formed to support that of the British Medical Association; but, judging by the cases quoted on the spur of the moment by several members present at the meeting, I venture to think it would have been better to have issued circulars asking for information and cases to support their argument, the immense necessity for which is of undeniable public importance.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

REMOVAL OF PAROTID TUMOUR; SUBSEQUENT SALIVARY FISTULA.

By L. A. LAWRENCE, F.R.C.S. ENG.

A MAN of middle age came to the Western General Dispensary early in November, 1893. He had a tumour in his left parotid region about the size of a small orange. It was of four years' duration and presented the usual signs of an innocent enchondroma. The patient desired its removal on account of its unsightliness. After watching the case for a short time I decided to operate, and accordingly on Nov. 16th the tumour was removed with ease and turned out to be an enchondroma. A line over the most prominent part of the swelling was chosen for incision; this was three inches long, and extended from just below the tragus of the ear to a point midway between the angle of the mouth and the angle of the jaw. Only the superficial integuments were incised, and immediately below them the capsule of the tumour presented. The mass itself shelled out. There was no hæmorrhage, and the facial nerve was not seen. The wound was washed out and the skin brought together along the whole line of the incision with horsehair sutures. The patient made an excellent recovery. The dressings were soaked through on the first night, and this condition was observed each time they were changed. Owing to staining the true nature of the discharge was not appreciated till four days after the operation, when the wound having healed in nearly its whole length the clearness of the fluid escaping at once showed it to be saliva. The small salivary fistula was situated in the line of the incision about one inch from the ear. This condition continued for five weeks. On Dec. 10th I probed the left duct of Steno from the mouth; there was considerable difficulty in finding the opening, much more so than on the right side. A fine probe entered about two inches and did not point towards the wound. Between the 10th and 15th a probe was inserted twice again. The house surgeon, Mr. Jackson, then gave him some belladonna in hopes of reducing the flow of saliva. The quantities taken were fifteen minims of the tincture on Dec. 15th. Then twenty minims each day till Dec. 21st, when the drug was omitted; from then till the 23rd twenty-five minims were taken daily. After this date the drug was stopped. On Dec. 27th the saliva ceased to run from the wound, which then closed spontaneously. I have brought the case forward on account of several curious features it presented. 1. As to the cause of the flow of saliva. The incision was quite superficial, and the facial nerve, except for, perhaps, some fibres on the surface, was quite intact. It may be doubted therefore whether Steno's duct was the source of the flow. A possible glandula socia may have been cut, but I was not aware of any such proceeding at the time of operation. 2. The influence of the belladonna treatment. After the first dose the patient said less saliva flowed through the opening. The first dose, however, was given the same day, when the last probing took place. There was never any dilatation of the pupils and only a trifling dryness of the mouth on waking in the morning, not sufficient for its being considered due to the drug. There were no other physiological effects of belladonna observable.

Then, again, the flow did not cease till five days after the medicine had been discontinued. Lastly, one may ask, What effect had the probing of the duct? To my mind none. If the duct had been cut probing the distal portion would not have helped the saliva to flow through it. If it had not been cut the saliva could not have escaped from it. I have lately again seen the patient, who is in excellent health in every way.

Harley-street, W.

REMARKABLE GUNSHOT INJURIES.

By J. G. STRACEY FORREST, L.R.C.P. LOND.,
M.R.C.S. ENG.

ON Jan. 18th, 1895, being in the vicinity, I was called by the police to see the body of a man found dead on the beach at St. Leonards. He was tall and stout, and apparently about thirty-six years of age. On examining the body, which was still warm, I found the whole of the left side of the face blown away; the roof of the mouth and also the cranial bones on that side were broken into fragments, enormous damage being done to the brain substance, which was exposed. Although the terrific force succeeded in producing such terrible destruction it nevertheless failed to produce any external lesion of the scalp. The whole scalp covering the calvarium was intact, there being an utter absence of external injury beyond that already mentioned on the left side of the face, although the cranial bones on that side and in front were so freely broken and loose. I also found about four inches below and one inch and a half internal to the left nipple a circular wound with charred edges, from which fat protruded, but no great hæmorrhage had apparently taken place. There was a corresponding hole in the waistcoat, shirt, and vest. On Jan. 20th, in conjunction with Dr. Kenyon, a post-mortem examination was made. We found the seventh and eighth ribs smashed, but the contents of the chest were uninjured. On examining the wound, which led straight in, we found the two wads covering the shot and powder and several small shot, apparently sixes, embedded in the fat, muscles, and tissues, but no perforation of the stomach or intestines was discovered. He was found lying on the beach on his back by a coastguardsman, with a double-barreled 12-bore gun lying between his legs, the muzzle resting on his stomach and inclined to the left. The right barrel had been discharged, but the left was still loaded. It appears that he must have first discharged the gun at his breast, but, this not proving immediately fatal, reloaded, placed the barrels in his mouth, and fired again, causing instantaneous death.

ROYAL FREE HOSPITAL.

ACUTE INTUSSUSCEPTION IN AN INFANT AGED FOUR MONTHS; LAPAROTOMY; RECOVERY; REMARKS.

(Under the care of Mr. E. W. ROUGHTON.)

WE have for many years advocated the publication of cases of intussusception which have been submitted to operation, for the list of recoveries after abdominal section for this condition, at any age, is still a small one, and information is required on several heads. The case recorded below is especially worthy of notice, because, so far as we can ascertain, the patient is the youngest on whom laparotomy has been successfully performed for that condition. Dr. Kammerer¹ and Mr. Howard Marsh² have each recorded a success after operation in a child aged six months; but it is well known that abdominal section is only

¹ Medical Record, New York, 1890, p. 114.

² In 1875.

too often followed by a fatal result when the patient is under the age of two years. The attainment of success in children is not entirely dependent on the promptitude with which laparotomy is performed after the child has come under observation, although the duration of the disease does influence the prognosis most seriously. We have seen laparotomy carried out within six hours after the patient showed symptoms of the intussusception; reduction was easily effected: the manipulation required was comparatively slight, took but a short time, and the surroundings were favourable, yet the child died in a few hours with cerebral symptoms, not due to visible organic disease. There was no peritonitis, and the condition of the parts involved was satisfactory. We do not think this experience unusual. Shock is also a result of operation much to be feared in children. Whilst there are without doubt cases in which the patient would have died but for the operation which permitted reduction to be promptly and certainly effected, the result of abdominal section has not been so satisfactory that we can afford to discard the use of injections of air or fluid, which have frequently proved effectual. We are strongly of opinion that these measures should be tried in all cases where the symptoms have been in existence for less than forty-eight hours, and that laparotomy should be recommended if injection has failed. We do not discuss this question more fully as we have often brought it forward in the columns of THE LANCET.*

A female infant aged four months was admitted to the Royal Free Hospital on Dec. 27th, 1893. On the previous day she had been suddenly seized with pain in the abdomen and vomiting, soon followed by the passage of blood per rectum. The following was its condition on admission. The child was well nourished and not collapsed. The abdomen was tense but not distended; in the left iliac region a fulness but no distinct tumour could be felt. Per rectum a soft, elastic mass could just be reached towards the left iliac region; the rectum itself was empty. An operation was performed twenty-four hours after the onset of the symptoms. Chloroform having been administered the abdominal tumour could be distinctly felt. No attempt was made to reduce the intussusception by injection or inflation. The abdomen was opened in the middle line. On introducing the finger the mass was at once found and brought out at the wound; reduction was easily effected by kneading from below upwards. The invagination extended from the ileo-caecal valve to the sigmoid flexure. Rapid and complete recovery ensued. The patient was last seen six months after the operation; there was then a small umbilical hernia the result of whooping-cough, but no bulging of the scar.

Remarks by Mr. ROUGHTON.—I attribute the recovery of this child to the early performance of abdominal section without previous attempts at inflation or injection. Many cases of acute intussusception have been cured by inflation or injection, and it is quite possible that this case might have been cured by one of these methods; on the other hand, many cases have been killed, either directly by bursting the intestine or indirectly by the waste of time entailed by unsuccessful attempts at reduction. The fatality of acute intussusception varies directly as the length of time allowed to elapse before reduction is effected. I think that inflation should be discarded, that injection should be reserved for the very earliest cases, and that immediate operation should be performed in all cases of twenty-four or more hours' duration.

ROYAL BERKSHIRE HOSPITAL.

PERFORATION OF A GASTRIC ULCER; OPERATION; RECOVERY; REMARKS.

(Under the care of Mr. J. HOPKINS WALTERS.)

WE publish with pleasure the account of a successful operation for the cure of perforating gastric ulcer. The promptitude of diagnosis and treatment is answerable for the happy result, and we have nothing to add from a scientific point of view to Mr. J. Hopkins Walters' remarks.

A woman aged twenty years was admitted into the Royal Berkshire Hospital, Reading, on the morning of Sept. 16th, 1894. She had been sent by Dr. G. H. R. Holden, who suspected perforation of a gastric ulcer. She had suffered from gastrodynia

and vomiting after food for nearly four years. The evening previous to admission she had tea and bread-and-butter about 5 P.M., and whilst walking about 9 P.M. was seized with sudden pain in the left costal region. She felt sick, but did not vomit. On her admission the temperature was 100° F. and the pulse 120, weak and irregular. She complained of pain at the margin of the left costal cartilages, transmitted to the left shoulder, which, however, was not severe except on movement. The abdomen was somewhat distended; the liver dullness was absent. There were general tympanites and slight tenderness over the whole abdomen, which was more marked over the region of the stomach. There was no marked collapse nor typical facial expression, and the legs were not drawn up, but abdominal respiratory movements were absent. At 10.30 A.M., after consultation, Mr. Walters opened the abdomen by a median incision in the epigastrium. The peritoneum was distended with flatus, which escaped when the cavity was opened. There was no general peritonitis. The stomach was easily reached and well pulled out, when on the anterior surface, about three inches from the cardiac end, towards the lesser curvature, there was seen a clean-cut, punched-out aperture the size of a cedar pencil in the centre of a thickened and hardened portion of stomach wall of the circumference of a half-crown piece. The edges of the perforation were almost cartilaginous in appearance and feel. There were no adhesions. No stomach contents were found in the peritoneal cavity, but the sponges brought up some pieces of lymph from the region of the spleen. The ulcer was doubled upon itself, in the long axis of the stomach, with the serous surfaces in apposition and the perforation in the centre of the fold. The serous membrane was united with a first row of Lembert's sutures, followed by an outer continuous suture, all in fine catgut. The peritoneal cavity was then washed out with weak boracic lotion and the abdominal wound sutured. A quarter of a grain of morphia was given by the skin. The progress of the case calls for little remark, recovery having been rapid and uninterrupted. There was slight chloroform sickness, the vomited matter being a blood-stained fluid. The temperature, which previously to operation was 100.4°, at once fell and never afterwards reached 100°. The patient was at first fed with rectal enemata, lemon-juice with water was used as a mouth wash, thirst was relieved by large injections of water, and morphia was continued hypodermically. On the 18th, two days after the operation, cold water was allowed by the mouth in very small quantities often repeated, as thirst was urgent. On the 23rd, seven days after the operation, one ounce of chicken broth every half hour was permitted by the mouth and the quantity gradually increased. She was next allowed arrowroot three times a day, and on Oct. 5th ate some boiled sole without discomfort resulting. The wound was dressed on the seventh day and found to be completely united. The only drawback during convalescence was some phlebitis in the left saphenous vein, leading to slight swelling of the leg, which soon passed away. On Dec. 24th she was discharged, having regained strength and flesh. She was cautioned to keep chiefly to a soft, easily digested dietary.

Remarks by Mr. WALTERS.—This case was a particularly favourable one by reason of the long time that elapsed from the last meal to the occurrence of perforation, this taking place on an empty stomach, of immediate medical attendance with accurate diagnosis, of prompt transportation to hospital, and of early operation. The patient's ability to endure the operation was, therefore, at its best, although she was quite a delicate girl. In performing the operation I dealt with the conditions on their merits without adhering strictly to precedents. On finding the hole I first considered whether I should follow the lead of some operators by excising the entire ulcer. This would have left such a formidable opening in the organ, and the case looked so favourable owing to the absence of complications, that I was unwilling to run the risk of making it more grave by such a procedure. My judgment in this matter seems to be justified by the resulting continuous convalescence. I also abstained from the fashionable "procedure of precision" of injecting water into the viscus to see whether my needle-work had produced an absolutely impervious seam. I think this in most cases a needless precaution on account of the rapid adhesion of serous surfaces to one another and the early perfection of such sealing. Where the stomach is found to contain food I think the proper thing is to thoroughly empty and wash it out. These, with perfect cleansing of the peritoneal cavity, are essentials to success, and there is no chance of leakage from an empty stomach

* THE LANCET of Jan. 26th, 1889, Nov. 29th, 1890, May 23rd and June 13th, 1891, and Feb. 24th, 1894.

where the sutures are inserted with judgment and care. In this case, with perfect impunity, I permitted the ingestion of small quantities of water so early even as the second day, by which time peritoneal adhesions are tolerably firm. The result from first to last has been most gratifying, and I am glad to be able to add one more to the small list of successful operations for the cure of perforating gastric ulcer.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Endosteal Sarcoma of the Patella.—Fœtus with Reptilian Characters in Sexual Ducts.—Adenoma of Lip.—Portal Thrombosis and Hepatic Infarction.—Exhibition of Specimens.

AN ordinary meeting of this society was held on Feb. 19th, the President, Dr. PAVY, being in the chair.

THE PRESIDENT alluded to the loss sustained by the society in the death of Mr. Hulke, a past president of the society. He referred to Mr. Hulke as possessed of great ability and of high and varied mental attainments. At the time that he was president of the Pathological Society he was also president of the Geological Society, and he occupied a prominent position among palæontologists. Mr. Hulke was a man of the highest rectitude of character and of an evenly balanced mind, whose opinion could be relied upon with the greatest security. A resolution of the council that expressions of sympathy should be conveyed to Mrs. Hulke was carried *nem. con.*

Mr. D'ARCY POWER showed for Mr. ROBERT JONES of Liverpool an Endosteal Myeloid Sarcoma of the Patella. The new growth involved the whole of the knee-cap, but the articular cartilage remained and was healthy. The tumour was solid. The tibia, fibula, femur, and the articular surfaces of the knee appeared to be quite healthy. The patient was a girl aged twenty who had twice injured her knee by falling upon it. The growth was of four and a half years' duration and its origin dated from the last injury. Mr. Robert Jones at first thought that the growth was an enlarged bursa patellæ, so closely did it simulate fluctuation. The skin over it was blue and brawny, however, and the hollow around the patella was obliterated in a manner which was unusual in the case of such enlarged bursæ. The tumour continued to grow and Mr. Jones amputated the thigh in its middle third. This was the first case of endosteal tumour which had been brought before the society. Mr. Power knew of only one other specimen, and that was in the Hunterian collection, to which it had been presented by Sir Astley Cooper. The Hunterian specimen, however, presented the ordinary cystic character of myeloid sarcomata, whilst the present growth was solid. It was doubtless this solidity which had caused the difficulty in recognising it, for although it was very soft there was no eggshell crackling.—Mr. SHATTOCK said that there was a specimen in the museum of St. Mary's Hospital, which was described and illustrated by Mr. Pepper. It was a primary sarcoma arising in the patella and leaving the cartilage intact.—Mr. BOWLBY said that where collections of blood existed in these sarcomata they usually grew very slowly, while if the growths were solid they progressed more rapidly.—Mr. D'ARCY POWER, in reply, said that although the growth was solid it had existed nearly five years.

Mr. S. G. SHATTOCK exhibited a Male Fœtus showing Reptilian Characters in the Sexual Ducts. The specimen showed a malformation of the sexual ducts which came in the category of abnormal arrest at a normal stage in human development, and which he regarded as best explained on the principle of atavism or reversion to an ancestral type. The malformations in question were associated with extraversion of the bladder and prolapse of the posterior segment of the intestine, which terminated blindly at the umbilicus. The particular characters referred to, however, consisted: 1. In a remarkable elongation of one of the kidneys, recalling the condition in certain lacertilia and ophidia, and it was noteworthy that the kidney so altered was the right, for in ophidia the right kidney was normally much longer than the left. 2. In the persistence of both Müllerian ducts, which remained quite distinct from one another throughout and opened in the neighbourhood of the ureters on the extroverted surface. This resembled the

persistence of both oviducts in an ununited condition in the females of reptilia. 3. On one side the vas deferens opened into the ureter. This was a persistence of the primitive embryological condition in man, and it represented what was a permanent one in the males of lacertilia, where these canals opened together in the cloaca. There were in addition two blind sacs representing the anal pouches of reptiles. Mr. Shattock observed also that the extreme degree of hypospadias in the human subject, though usually regarded as strictly pathological, might really be viewed as a reversion to a reptilian type, for in the crocodile and tortoise the penis was single and the urethra represented merely by a groove on the lower or posterior surface, near the base of which lay the openings of the vasa deferentia in the cloaca.

Mr. DUNN showed a specimen of Adenoma of the Lip removed from a young adult who was admitted into Guy's Hospital in December. The growth had existed during the greater part of the patient's life. It was firm, elastic, encapsuled, rather soft at one part, and shelled out easily. Microscopically the tumour was composed of a large quantity of fibrous tissue and contained numerous spaces lined with one or two layers of epithelium. There was no cartilage.

Dr. N. PITT showed two specimens of Portal Thrombosis and Infarction of the Liver. The first specimen was removed from a man aged thirty-six, admitted into Guy's Hospital after an injury to the abdominal wall. He had a strangulated scrotal hernia, associated with bruising of the bowels. Death resulted from membranous enteritis and paralysis of the bowel. In the right lobe of the liver there was an infarcted area, with a thrombosed portal vein in its centre. Though the liver showed no bruising, yet probably the blow injured a branch of the portal vein and so gave rise to the thrombosis and infarction. Dr. Pitt showed a second specimen taken from a patient who had been under Dr. Washbourn's care. The man was aged forty-eight, and after recovering from an attack of hemiplegia he succumbed to a second seizure. Two patches of thrombosis were found in the aorta and other thrombi were present in the renal, splenic, and cerebral arteries. The greater portion of the portal vein and the right middle hepatic vein were thrombosed. The liver showed numerous infarcted areas, some being deeply engorged and others pale. Though the whole splenic artery was blocked, yet infarctions only occurred here and there in the spleen, and the same remark applied to the brain.—Dr. CYRIL OGLE said that in a similar specimen he had shown he attributed the infarction to a septic condition of the blood, which therefore extravasated readily.—Dr. ROLLESTON, in a case of occlusion of the main branch of the splenic artery, had found only disseminated infarcts in the spleen. A similar condition he had found associated with thrombosis of the splenic vein.—Dr. PITT, in reply, said that in one of the cases shown there were adhesions, and this permitted a considerable amount of collateral circulation.

The following card specimens were shown and described:—
Dr. W. W. ORD: Hydronephrosis due to Stricture of Ureter.

Dr. N. PITT: (1) Kidneys increased Fourfold by Acute Nephritis; (2) Renal Calculi in Infants.

Dr. C. ARKLE: Ulcerative Colitis.

Mr. Dunn: Uric Acid Calculi from a Child aged eighteen months.

Dr. CYRIL OGLE: Two specimens of Gastro-jejunostomy for Carcinoma.

HUNTERIAN SOCIETY.

Exhibition of Cases.

AN ordinary meeting of the Hunterian Society was held at the London Institution on Jan. 23rd, Mr. J. CHARTERS SYMONDS, President, being in the chair.

Sir HUGH BEEVOR showed a case of Tumour of the Left Loin.

Mr. OPENSHAW showed a case of Congenital Sacral Tumour in a child aged sixteen months, which projected backwards in the middle line over the coccyx as a globular swelling the size of a walnut, translucent, fluctuating, and unaffected by crying. Digital exploration showed that the tumour passed up in front of the sacrum nearly as high as its base. Mr. Openshaw also showed a case of Multiple Osteitis, affecting both tibiae, both fibulae, both ulnae, the left humerus, and the lower part of the shaft of the right femur in a boy aged ten, who presented no evidence of scrofula or congenital syphilis and who gave no history of injury.

Dr. WOODS showed three Choreic patients (females) aged seventeen, fifteen, and eight years and a half who had been much improved by hypnotism. He detailed the results of eleven cases of chorea which he had treated. Of these, nine have recovered, one has relapsed, and one was too recent to be of value.

Mr. POLAND showed a case of Excision of the Isthmus and (portion of) Lateral Lobe of the Thyroid. The patient, a woman aged thirty-seven, had noticed swelling of the right side of the neck about the middle of last August, but only lately had it become painful and "pressed upon her throat," as she described it. She also had pain during deglutition, or rather pain was present just on the commencement of this act. This interference with the oesophageal function was likewise marked by the desire to perform the act of deglutition, which was very frequent and at last became most distressing. There was at first but little difficulty in breathing—in fact, only a few days before she was first seen, at the commencement of last December, did any marked symptoms of interference with expiration present themselves. She had then only some occasional choking sensation. However, between that time and the date of the operation on Dec. 17th she had two or three bad attacks of dyspnoea, which were so severe that she thought she was about to be suffocated. The tumour then measured four inches obliquely from above downwards and three inches obliquely side to side. With a median incision three inches and a half in length in front of the trachea, which, together with the thyroid, was pushed over to the left side, it was possible to remove the whole of the enlarged isthmus and nearly two-thirds of the right lateral lobe. A notch indicated the junction of the hypertrophic isthmus and the left lobe. The thyroid tissue was divided at this point by a blunt director; a similar course was adopted to remove the mass on the right side; a large rounded portion was left behind for fear of any subsequent myxodematous changes. During the removal of the mass projecting behind the sternum a cyst one inch and a quarter in diameter was displaced from behind the bone, and ruptured during removal. It contained six ounces of brownish fluid. No ligatures were used either for the isthmus or lateral lobe, and there was no hæmorrhage. One or two small branches of the anterior jugular vein and a few other small vessels at the upper end of the tumour required to be tied. These were the only ligatures used, with the exception of the buried silk ligatures employed to bring the different fascial layers together. The wound was closed by silkworm gut without any drainage, and was found to have healed by first intention at the first dressing on the seventh day. The patient immediately after the operation lost all her distressing symptoms, and had remained well since. Mr. Poland thought this might be considered an ideal operation upon such conditions of the thyroid gland as were here to be dealt with, provided that the most rigid asepsis was carried out and the several layers of cervical fascia brought together in their normal relation carefully by deep sutures. By the latter means the cavity left after the removal of the tumour might be almost, if not entirely, obliterated (as in this case). The isthmus after removal was one inch and a quarter in width, and the left lateral mass rather more than three inches and a half. Microscopical sections made by Dr. W. Edmunds were exhibited. They showed normal thyroid tissue with normal vesicles.

Mr. HUMPHREYS showed a patient convalescent from Typhoid Fever complicated with Empyema.

Mr. SYMONDS showed a patient in whom he had Ligatured both Common Carotid Arteries. The history of the case briefly was that during an operation for the removal of the superior turbinated bone by a throat specialist profuse hæmorrhage occurred, which was arrested by firmly plugging the nares and nasal fossa. A few days subsequently he came under Mr. Symonds' care with excessive chemosis and proptosis, and with loss of vision in the left globe and a very loud bellows murmur over the whole of the left temporal and frontal regions. Traumatic aneurysm of the cavernous sinus was diagnosed and the left carotid ligatured, with marked improvement. At a later date the symptoms again increased in severity and the right common carotid was ligatured, with a perfect cure. No bruit was now audible and no symptoms were complained of. With the exception that vision in the left globe was lost the patient was perfectly well.

Dr. ARNOLD CHAPLIN showed a case of Morbus Cordis associated with Pulmonary Phthisis.

BRITISH GYNÆCOLOGICAL SOCIETY.

Presidential Address on the Evolution of Obstetrics and Gynæcology.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 14th, Dr. CLEMENT GODSON, President, being in the chair.

The PRESIDENT delivered his inaugural address on the Evolution of Obstetrics and Gynæcology. At the commencement of his address Dr. Godson congratulated the society on having just entered its second decennial period, the foundation meeting having taken place on Dec. 27th, 1884, and the inaugural meeting on March 11th, 1885. He then passed in review the gynæcological references in the writings of Hippocrates, Celsus, Galen, Soranus, Paulus Aegineta, and Albucasis, and alluded to Philumenus, in whose work, quoted by Aëtius, occurs the first mention of a vaginal speculum. The instrument, however, is known to have been in use as early as the destruction of Pompeii, examples having been found in the course of recent excavations there. He described the imperfect knowledge of utero-gestation possessed by Hippocrates and Aristotle, who supposed that the womb was pouched, males being carried on the right side and females on the left. He continued:—

"In 1552 Thomas Raynald published in London 'The Byrth of Mankynd, otherwise named the Woman's Booke.' It is in reality a translation of the treatise, 'De Partu Hominis,' which appeared in 1532 and was originally written by Eucharius Rhodion. An earlier edition dated 1540 is ascribed to Richard Jonas, but this I have not seen. There are three or more editions of Raynald's book; I have the original one here. Our late distinguished Vice-president, Dr. Aveling, devoted considerable attention to it in his book on the 'History of Midwives.' Ambroise Paré, a noted French army surgeon in the sixteenth century, gives evidence in his writings that he was a practical obstetrician. Mauriceau, by his 'Traité des Femmes Grosses et de celles qui sont nouvellement Accouchées,' published in 1668, marked a new era in midwifery. He was the first to take notice of the obliquity of the womb as an obstacle to a speedy and safe delivery. The structure of the ovum and the problems of gestation fascinated the master mind of William Harvey, and claimed the attention of men worthy to rank with him, such as Naboth of Leipzig, Morgagni, Santorini, and William Hunter, the latter of whom was a learned and scientific rather than a great clinical obstetrician. In 1748 he was elected one of the surgeon men-midwives to the Middlesex Hospital, and soon afterwards to the British Lying-in Hospital. In 1764 he was appointed Physician Extraordinary to Queen Charlotte, and ten years later he published his great work, 'On the Gravid Uterus,' which had been twenty-four years in preparation. He died in 1783, aged sixty-five years. William Smellie, another famous accoucheur, was at first a general practitioner at Lanark, in Scotland, in 1716. Subsequently he studied midwifery for three months in Paris under Grégoire and settled in London. He did not become a fashionable physician, like his contemporaries, Hunter, Manningham, Manbray, or Douglas, but he did more for the advance of surgical obstetrics than any three men of his time. He is said to have first heard of the forceps in 1733. This instrument, however, is supposed to have been known to the Chamberlen family in the beginning of the seventeenth century, and to have been kept secret by them for nearly a hundred years. Prior to 1733 it was employed with great success by Mr. William Giffard, surgeon and man-midwife, for in this year Dr. Edward Hody, F.R.S., published a revised edition of Cases in Midwifery, 225 in number, 'which were for the most part attended with a great deal of danger and difficulty,' and to which Mr. Giffard was summoned by midwives. The dedication of the book bears date July 30th, 1733. In it are drawings of Mr. Giffard's 'extractor,' and also of an extractor as improved by Mr. Freke, surgeon to St. Bartholomew's Hospital from 1729 to 1755. This shows that in the early part of the eighteenth century midwifery was practised by surgeons on the staff of St. Bartholomew's Hospital. Mrs. Elizabeth Nihell, professed midwife, in her treatise on 'The Art of Midwifery,' published in London in 1760, says that Mr. Giffard's extractor is supposed by Levret and others to be nothing more than the 'windowed' forceps, which had long been known. Edmund Chapman, surgeon, also in 1733, published an essay 'On the Improvement of Midwifery,' in which he describes several forceps

of very dissimilar patterns, and claims for himself the credit of discarding the screw connecting the two blades. In 1724 appeared 'The Female Physician, containing all the Diseases incident to that Sex in Virgins, Wives, and Widows,' by John Maubray, M.D. Denman says that Dr. Maubray is reported to have been the first lecturer on midwifery in Great Britain. He gave lectures in his house in New Bond-street about 1724. Sir Fielding Ould, man-midwife, in a treatise on Midwifery in three parts, published in Dublin in 1724, was the first to describe the mechanism of labour in head presentation. The first lying-in hospital in London—viz., the British—was founded in 1749; the City of London Lying-in Hospital followed in 1750, Queen Charlotte's in 1752, and the General Lying-in Hospital in 1765. The first English obstetrical society was founded in 1825, with Sir Charles Clarke as its President, one of its objects being 'to raise to a proper and dignified station the practitioner in midwifery.' It had, however, to encounter strenuous opposition. Sir Anthony Carlisle, F.R.S., surgeon to the King and to the Westminster Hospital, published in the *Times* of May 1st, 1827, an 'Address to His Majesty's Judges, Coroners, and Justices of the Peace,' cautioning them against the worldly designs and the injurious practices of man-midwives. Similar arguments were used by other opponents, but the agitation was fortunately unsuccessful, and the first Obstetrical Society, after exertions continued during three years, secured the following points: (1) A recognition of the honourable position of obstetricians among the medical practitioners of the three corporate bodies; (2) an examination in midwifery by the Apothecaries' Company; (3) the admission of persons practising midwifery (being members of the College of Surgeons) to be eligible for a post on the Council; (4) the concession by the College of Physicians that Licentiates practising midwifery shall not be ineligible for the Fellowship of the College. The barriers to the undertaking of midwifery by men being thus removed, obstetric practice soon fell largely into their hands, as, in fact, had already been the case in France for more than a century. Midwifery and gynecology being essentially surgical, it is strange that those who profess and teach these subjects are ranked among the physicians in our great hospitals and medical schools. I referred to this anomaly in my presidential address in the Obstetric Section of the British Medical Association in Belfast in 1884, and I hope that the time is not far distant when the title of obstetric surgeon shall be substituted for that of physician accoucheur, and when the obstetrician shall be ranked on the surgical side of the hospitals."

The following specimens were shown:—

Dr. MACNAUGHTON JONES: An Intra-uterine Non-pedunculated Fibroid, removed from a patient, aged thirty-two years, recently married.

Dr. LEITH NAPIER: Senile Uterus, removed by vaginal hysterectomy for Procidencia.

HARVEIAN SOCIETY OF LONDON.

Relapsing Typhlitis.

A MEETING of this society was held on Feb. 7th, the President, Sir JOHN WILLIAMS, being in the chair.

Mr. TREVES gave an account of an additional series of eighteen cases of Relapsing Typhlitis in which he had removed the appendix during the quiescent period. He pointed out the morbid conditions of the appendix which are most commonly met with in this affection, and mentioned the fact that when once an abscess had formed the trouble very seldom indeed relapsed. The difficulties of the operation depended mainly upon adhesions. If no adhesions existed the procedure was most simple. In some of the cases in the series perforations in the caecum and in the ileum had been laid bare during the operation and had been closed by sutures. Many concretions had been removed, and in one instance the appendix was found firmly attached to the rectum. Mr. Treves alluded to the medical measures employed to ward off attacks and especially to the questions of diet, the avoidance of milk, the care of the bowels, the importance of perfect mastication, the use of such an intestinal antiseptic as salol (in a powder of ten grains), and the employment of massage.

The PRESIDENT inquired upon what grounds Mr. Treves maintained that the occurrence of an abscess tended to cure the condition, and, commenting upon the subject of diet, said that he was unable to join in Mr. Treves' strictures upon milk as a food for invalids.

NORTH-WEST LONDON CLINICAL SOCIETY.

Exhibition of Specimens and Cases.

A MEETING of this society was held on Feb. 13th, Mr. MAYO COLLIER, in the absence of the President, Sir R. Quain, being in the chair.

Dr. KNOWSLEY SIBLEY exhibited the Supra-renal Capsules of a woman in whom the symptoms of Addison's disease had developed rapidly, leading to death suddenly and by exhaustion.—Dr. HARRY CAMPBELL pointed out that the sudden death in this case was noteworthy.—Dr. GUTHRIE dwelt on the fact that the degree of pigmentation in Addison's disease was not a guide in prognosis. He related cases of Bright's and Graves' diseases in which very extensive pigmentation had been observed.

Dr. STOWERS showed a case of Lupus Erythematosus, and described the method of scarification.—Mr. Jackson Clarke, Dr. Wilbe, and Mr. Collier took part in the discussion.—Dr. STOWERS also showed a rare form of Tertiary Dermatosyphilis, simulating erythematous lupus.

Dr. HARRY CAMPBELL showed the Heart of a Man who had died from acute aortic obstruction, there being no evidence of regurgitation.—Dr. GILL related two similar cases occurring in one family.

Mr. MAYO COLLIER showed a case of Contracture of the Posterior Tibial Group of Muscles in a girl who had infantile paralysis and advocated division of the tendo Achillis in such cases as a complete and sufficient treatment.—Dr. CAGNEY objected that there were a great many cases in which much more should be done in order to develop the immature muscular fibres, and contended that in this respect the subjects of infantile paralysis were lamentably neglected.—Mr. COLLIER also showed a case of Flatfoot, and demonstrated the mechanism of its production upon the skeleton.—Mr. JACKSON CLARKE observed that he had found a system of gymnastic exercises of great service in flatfoot.

LIVERPOOL MEDICAL INSTITUTION.

Ligature of Right Femoral and Left External Iliac Arteries for Aneurysms.—Two Cases of Beri-beri.—Intussusception, successful approximation by Murphy's Button.—Carcinomatous Stricture of Transverse Colon, successful approximation by Murphy's Button.—Fourteen Cases of Excision of the Rectum for Cancer.

A MEETING of this society was held on Feb. 14th, the President, Mr. CHAUNCEY PUZEY, being in the chair.

Mr. ROBERT JONES showed a patient in whom he had tied the External Iliac Artery on the left side for Femoral Aneurysm, and also the Femoral Artery on the right side for Popliteal Aneurysm. He applied a double ligature on the external iliac by the extra-peritoneal method. The patient was able to resume his work in two months, and had had no circulatory disturbance.

Dr. ABRAM showed two cases of Beri-beri. The patients were the captain and mate of a Norwegian barque just arrived in Liverpool after being some two months on the coast of Brazil. The captain showed the typical signs of neuritis, most marked on the legs. The mate still had muscular tenderness in the calves, but the knee-jerks had returned. Both gave a history of oedema, which in the captain was limited to the legs and in the mate was general. Both had had palpitation and dyspnoea, and the captain had severe vomiting for five days. Inoculations from the blood were negative. No malarial organisms were found on examination of fresh blood. Rapid improvement was taking place under general tonics and regular massage.

Mr. BANKS related the case of a boy seven years of age who for some little time had suffered from irregularity of the bowels with abdominal pain after going to stool. A week before Mr. Banks saw the case the child complained of pains all over him and general malaise. Two days later he had severe abdominal pain and vomiting, and from that time no

¹ Obstetrical Society's Transactions, vol. 1.

proper motion or any flatus had passed. An enema was given which brought away blood and mucus. On admission into hospital four days later the abdomen was moderately distended, and there was complete obstruction. A fulness could be felt to the right of the umbilicus, which might be due to colitis or appendicitis, but with the history of the passage of bloody mucus it was thought to be an intussusception. The following day an anæsthetic was given; the abdomen then relaxed and a sausage-like swelling could be plainly felt to the right of the umbilicus. The abdomen was opened in the middle line and an intussusception of the ileum was found about eighteen inches from the cæcum. The bowel was black and gangrenous, so it was cut out, and the ends were joined by a Murphy's button. The boy rallied well and was able to take a fair amount of nourishment, his progress being slow but steady. The button was passed on the twenty-first day, and he returned home on the thirty-eighth day.

Mr. GEORGE HAMILTON related the case of a man aged thirty-three years who had suffered from symptoms of subacute Intestinal Obstruction due to a Carcinomatous Stricture in the centre of the Meso-colon. Four inches of colon were removed, the ends being approximated by the inch and a half Murphy's button. The patient made an uneventful recovery; the button was passed on the twenty-fourth day.

Mr. PAUL read a paper on Excision of the Rectum for Cancer based upon fourteen cases. Of these, three were examples of simple low excision as advocated by Mr. Harrison Cripps, two were the same with part of the vagina, three were high operations after Kraske with approximation, and the remaining six were high operations without approximation. The amount of bowel removed varied from two to eight inches. The mortality was 14 per cent. Six had died since operation, the average duration of life being one year and eight months. Six were living at periods varying from one year and a quarter to upwards of ten years. He thought the operation very much more successful than for advanced cancer of the month, and strongly recommended the high operation first suggested by Kraske, but independently performed a little later in this country by Alexander. Mr. Paul showed a new rectal truss which he had had made for patients who subsequently suffered from incontinence or prolapse.—Dr. ALEXANDER congratulated Messrs. Banks, Hamilton, and Paul on the advances in surgery indicated in their papers. He thought that Mr. Paul's results were excellent, and the prolongation of life undoubted, and not only was life prolonged, but it was life worth living. He thought that the patient was far more comfortable and more benefited by excision than by colotomy. He had a case working for ten years after Kraske's operation, and one patient rejected in London and sent home to die had nearly three years of comfort and was able to shoot and fish before recurrence carried him off. In his experience the disease was much more common in males than in females.—Mr. PAUL thought that many children could not bear the removal of a large piece of bowel as in Mr. Banks' case, and one usually had to choose between the establishment of a fecal fistula and the more simple and safe operation introduced by Mr. Barker. With regard to Mr. Hamilton's case Mr. Paul thought that there was reason to hope for a good result, not only in the first instance, but later, as these small ring strictures were less malignant than most other forms of cancer. He thought Murphy's button the best method of approximating large intestine, and would advise its employment in colectomy when the growth was small and the symptoms of obstruction not severe; but when the growth was advanced or the abdomen considerably distended he thought it much wiser and safer to bring the ends of the bowel out and approximate later.—Mr. BANKS said that the great advantage of Murphy's button is that time is saved, which is often the principal element in success.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Mania following Pleurisy. — Operations on the Mastoid Process. — Dilatation of the Cervix Uteri. — Flexor Spasm of Hand. — Exhibition of Cases and Specimens.

A MEETING of this society was held on Feb. 1st, Dr. E. WEST SYMES, President, being in the chair.

Mr. BATES read the notes of a case of Acute Mania following Dry Pleurisy in a girl aged twelve years.

The maniacal symptoms came on the day following the reduction of the temperature to normal. The maniacal symptoms quickly gave way to treatment with sedatives, but the delusions were a week before they disappeared. The family and previous history pointed out instability of the nervous system in the patient, and accounted for the post-febrile mania following what was only a mild attack of pleurisy.—Dr. BARRS thought that mental disturbances frequently followed febrile conditions, no matter from what cause arising, as also after surgical operations and in cardiac cases.—Mr. WARD, in discussing the analogy of Mr. Bates's case with cases following operations, noted the youth of the patient. He had never met with a case of mental disturbance in one so young.—Dr. CHURTON used morphia hypodermically unless contra-indicated, and then immediately administered chloroform for two or three minutes in cases of acute delirium, gradually increasing the dose of morphia until a continuous sleep of six or eight hours was obtained.—Mr. Godfrey Carter, Dr. Gordon Black, Dr. Mantle, the President, and Dr. Bedford Pierce (who mentioned a case of mania accounted for by constipation) also took part in the discussion.

Dr. ADOLPH BRONNER read a paper on the Various Methods of operating on the Mastoid Process and the Indications for the Same. He described the original operation of Schwartz, which was practised from 1873 to 1889, how Kustner modified the operation by removing also the posterior wall of the external meatus, and how Bergmann removed also the pars epitympanica, or upper wall of the external meatus. Stacke in 1890 altered the operation considerably. He pulled out the whole of the cutaneous external meatus and opened up the attic and mastoid antrum from the external meatus. He used a bent chisel and protector. The middle ear, attic, and mastoid antrum were thus made to form one large cavity. This cavity was then lined with the cutaneous external meatus. Schwartz modified this operation by opening the antrum first, and then from this cavity he removed the posterior wall of the external meatus and the pars epitympanica. He only removed the posterior part of the cutaneous external meatus, and lined the newly formed cavity with this part, cut into two flaps. In cases where the attic was diseased Stacke's or Schwartz's modified operation was the most satisfactory. The chisel and mallet were now universally used. Macewen preferred the rotatory burr.

Dr. BRAITHWAITE read a paper on a point in the Dilatation of the Unimpregnated Cervix Uteri. The point was that when the unimpregnated cervix was dilated (for whatever purpose), it was much easier and more satisfactory to do it on the last day of the menstrual period or when the discharge had just ceased. At this time the work was already done to some extent, and the tissues were so soft and elastic that dilatation could be accomplished to almost any extent in about twenty minutes, provided the patient was under an anæsthetic.

Dr. CHURTON showed a girl aged twenty, tall and well formed, but with small cranium and rather childish manner, not robust, who had constant Flexion of the Wrist and Fingers, the thumb being usually laid across the palm. Her father died from phthisis aged thirty-two, a sister aged twenty-two suffered from phthisis, and a sister aged eight from diabetes. During childhood she had frequent nightmare. After one of such dreams, followed by a severe screaming fit, at the age of ten, she was found to be hemiplegic on the right side, her mouth was twisted, it is said, and saliva ran from it. Speech returned next day. Chorea occurred on the left or sound side in a few days, and lasted some weeks. The right leg recovered in a few months. She could always move the right shoulder. When first seen the legs were equal, and she had slight right facial paralysis. The left part of the face was the first to move. The bones of the right arm and hand were equal to those of the left; the muscles were smaller, but reacted to weak coil shock, also normally to cells KCC > ACC. There were no tremors or athetosis. The flexion was easily overcome usually, but was maintained during sleep and when the wrist was forcibly flexed (not always). When asked to do so she extended the fingers and thumb, almost completely at first, and afterwards much less readily. The pupils showed the trace of dilatation often observed in functional cases.

The following cases, pathological specimens, &c., were shown:—

Dr. BARRS: 1. Primary Carcinoma of Liver. 2. Patient suffering from Paralysis of the Right External Rectus who had recently recovered from paraplegia following influenza.

Dr. ADOLPH BRONNER: Case in which the Carotid had been tied for Pulsating Exophthalmos.

Dr. TREVELLYAN: Case of removal of Malignant Growth from the Larynx. (Operation performed by Israel of Berlin eight months ago.)

Mr. MAYO ROBSON: 1. New form of Oesophageal Bougie. 2. Case of Caries of the Spine, with twelve months' Paraplegia. (Laminectomy three years ago.) Recovery. 3. Case in which the Radius had been removed for Necrosis. 4. A Pencil removed from a Girl's Bladder after a fortnight's impaction.

Mr. LITTLEWOOD: Hydronephrotic Kidney removed by Abdominal Nephrectomy.

Mr. JESSOP: Extensive Epithelioma of the Penis.

Mr. HARTLEY: Extensive Epithelioma of the Penis.

Dr. BAXTER TYBIE: Hydatid Cyst of Abdominal Wall with Microscope Preparation of Hooklets.

Dr. T. WARDROP GRIFFITH: Paralysis of Deep Branch of Ulnar Nerve.

EDINBURGH OBSTETRICAL SOCIETY.

Extra-uterine Gestation.—Methods of Artificial Respiration in the New-born.—The Mechanism of Labour.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 13th, Dr. A. H. FREELAND BARBOUR, President, being in the chair.

Dr. HALLIDAY CROOM read a paper on Two Cases of Extra-uterine Gestation operated upon at the fourth month. The first case was that of a primipara aged twenty-seven years who had not suffered from any pelvic trouble previously to this illness. She began to suffer from irregular hæmorrhages with pain in the abdomen and gradual development of an abdominal swelling. On bimanual examination a hard mass was palpated lying to the left side of the uterus and immobile; the sound passed three and a half inches into the uterus. At the operation the abdomen was opened in the middle line (he would have now preferred a lateral incision) and the sac exposed. On touching this with the knife the bleeding was so profuse that it was evident this was the site of the placenta, and it was cut through with the thermo-cantery. The clot was cleared out and the placenta detached, but no fetus or cord could be found. On passing the finger towards the pouch of Douglas a second sac was found, but it only contained blood-clot, with no fetus. The sacs were washed out, the opening stitched to the abdominal wall, and the cavity packed with iodoform gauze. The patient suffered severely from shock, but afterwards made a good recovery. The placenta was found microscopically to have the villi very much enlarged and some with myxomatous degeneration. The case was one of tubal pregnancy, with rupture into the broad ligament; the fetus had disappeared owing to the myxomatous degeneration of the chorion, as similarly occurs in intra-uterine cases. The second case had suffered from pelvic trouble for two years and recently from premenstrual pain and also during the flow. She had missed two periods. When lifting a heavy weight she felt something give way and developed symptoms of collapse, with slight vaginal hæmorrhage. Two other similar attacks occurred. A swelling was found on the left side and behind the uterus; decidua membrane was passed from the vagina. As the patient was very weak the operation was delayed. Another attack of collapse occurred and the abdominal swelling now extended to one inch above the umbilicus. It was decided to operate, when the sac was found adherent to the abdominal wall and contained blood-clot, which was turned out, and a second sac found higher up. This contained the fetus, of three and a half to four months' development, and the placenta, which was easily stripped off. The sac was washed out and packed as before. The case was evidently extra-peritoneal. The patient succumbed.

Dr. R. C. BUIST read a paper on Methods of Artificial Respiration in the New-born. He analysed the different systems that have been advocated by different writers. Schultze's plan had been attended by fracture of the clavicle, and death had occurred during its demonstration on a fetus. Dr. Buist described a method which he had practised with success. The child was placed face downwards on the hand of the practitioner, with its head away from him, and artificial respiration was effected by rolling it on to the other hand, the head then hanging backwards, and the sides of the thorax being compressed by the fingers as the child was

being transferred from the one hand to the other. Perseverance was of great consequence. One case was resuscitated one hour after apparent death.—The PRESIDENT mentioned a case where fifty minutes elapsed before inspiration occurred and another twenty-five minutes before respiration was established.—Dr. FERGUSON advocated mouth-to-mouth insufflation (a handkerchief intervening), the nostrils being compressed and pressure kept up over the abdomen to prevent air from passing into the stomach.—Dr. CULLEN considered that pressure of the larynx backwards was sufficient to prevent this, and had seen cases where insufflation had quickly succeeded when Schultze's method had failed.

The PRESIDENT read a paper entitled a Study of the more recent Frozen Sections in their Bearing on the Mechanism of Labour and the Third Stage. Plates had been published of twenty-two sections showing the anatomy of labour, excluding pregnancies. In two cases of pregnancy the frozen section showed that the peritoneum did not descend into the pelvis in front. In two cases, also of pregnancy, the bladder was found to be partly above the brim of the pelvis. As regards the mechanism, it was found that some cases had the long axis of the uterus parallel to the spine, in others it was perpendicular to the axis of the brim. It seemed probable that the former position was that found in the intervals between the pains; the latter during the pain. Zweifel stated that the retraction ring coincided with the os internum, there thus being no lower uterine segment. But in order to form a bag of membranes these must be stripped off to a considerable extent. Zweifel's view seemed incorrect. In these frozen sections the retraction ring was not always recognisable. Zweifel, as a result of his study, considered that internal rotation was brought about by the varying thickness of the soft parts in the different planes of the cavity; but he made no reference to the direction given to the vertex by the pelvic floor. In all the sections with one exception the chin was apposed to the sternum, the exception being an occipito-posterior case, where there was divergence to one inch and a quarter. As a criticism it could be stated that flexion was not a motion, but an attitude, and that flexion was not an integral part of labour.—Discussion on this paper was deferred till the next meeting.

The following specimens were exhibited:—

Dr. KYNOCH: An Ovarian Fibroma with the Uterus and Appendages removed post mortem from a patient who died from another disease; microscopically the tumour was composed of white fibrous tissue.

Dr. R. C. BUIST: A Placenta with an Old Hæmorrhage between the Membranes and the Placenta in proximity to the Cord. There was no specific history in the mother, and no symptoms relating to the hæmorrhage could be found.

Dr. CROOM: A Myxoma of the Chorion removed from a patient aged fifty-four.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Case of Locomotor Ataxia from Injury.—Small-pox.—Some Small-pox Temperatures.

A MEETING of this Section was held on Jan. 11th, Dr. W. G. SMITH, President, being in the chair.

Dr. CRAIG exhibited a patient and read a short paper on Locomotor Ataxia due to Injury. A year ago the man fell while revolving on a horizontal bar and lost consciousness for about twenty minutes. Although the injury seemed slight, yet within a few months his arms and legs were markedly ataxic, cutaneous sensibility was lost in the limbs and, to a less degree, in the trunk, the knee-jerk was gone, and gastric and rectal crises were complained of, but no ocular symptoms appeared. In the absence of cerebral or ocular symptoms, and with a history of the rapid appearance of other symptoms, could the case, he asked, be called one of true locomotor ataxia?—The PRESIDENT said that this was a case in which the term "locomotor ataxia" was applied in a clinical rather than a pathological sense. It was hard to bring it into line with those cases commencing with affections of the cerebral nerves. The ordinary forms were cerebro-spinal, but in this case all the symptoms were spinal.—Dr. FINNY remarked on the rapid loss of sensation which happened in this case. One might suppose it to be a change in the

posterior columns of the cord also involving the posterior nerve roots. He thought that the wasting of the muscles was out of proportion to the length of time that the man had not used them.—Dr. PARSONS said that some of the patient's symptoms might perhaps be functional rather than organic. However, there was no doubt he had marked incoordination.—Dr. CRAIG briefly replied, stating he agreed with the President as to the difficulty of regarding this case as an ordinary one of locomotor ataxia.

Dr. O'CARROLL read a paper on the Diagnosis and Prognosis of Small-pox, based upon the experience of the cases treated in the Hardwicke Hospital during the present epidemic in Dublin and the much smaller epidemic of 1887-88. With regard to diagnosis the main difficulty occurred with cases of varicella simulating variola, or *vice versa*. In cases otherwise similar, and supposing the diagnosis to be made at one visit, the points which favoured the probability of the case being one of varicella were the following: the fact of the patient being a child (provided that good vaccination marks were present); the eruption being greater on the trunk than on the face; the eruption being more or less multiform, even in the same region, papules, vesicles, and crusts being seen together; the absence of papules on the horny skin of the palms and soles. As to prognosis, Dr. O'Carroll believed there was hardly any acute disease in which it was so uncertain until convalescence was established.

Dr. H. C. DRURY exhibited a series of Temperature Charts of Variola Cases. He divided them into three classes: (1) those with primary and distinct secondary fever; (2) those in which the initial fever was continued into a period of febrile state, of longer or shorter duration, but without any distinctive character; and (3) those in which the high initial temperature, lasting three or four days, was the only one seen. He pointed out that from a large number of observations he was unable to draw any conclusions from the temperature as to the severity of the rash, general symptoms, or length of time till convalescence was complete, as all three classes of temperature were seen in unvaccinated as well as vaccinated cases.—Dr. DAY said that in the early diagnosis between small-pox and chicken-pox the eruption of the throat was an important point. In the former a papule might be present on the soft or hard palate or on the tongue. In chicken-pox it was a vesicle.—Mr. HORNE said that he did not see why a patient suffering from small-pox should be any more liable to abortion than when suffering from any other fever. It was all a matter of temperature. Provided this did not exceed 104° F. the danger of abortion was not greater than in the other fevers. He thought that the eruption on the throat was a very important point in the diagnosis at an early stage.—Dr. PARSONS mentioned three cases. The first was that of a woman who had been treated for scarlet fever at the Cork-street Hospital, and who on recovery had been sent to one of the convalescent homes. Three days afterwards she fell ill again, and shortly after the eruption of small-pox appeared. Another was that of a little unvaccinated child who one morning was noticed to have a papular eruption on his body. The nurse stated that the child had seemed quite well on the previous day. He had considerable difficulty in deciding whether it was a case of chicken-pox or small-pox, but the abundance of the rash and the rise of temperature decided him in favour of the latter. The third case was that of a man who walked into the dispensary. He had been feeling unwell for three or four days, but did not give up work. He had a well-marked papular eruption but no rise of temperature, and affirmed that he then felt quite well. He had not been revaccinated, but had three distinct old marks.—Dr. J. W. MOORE said that the way the eruption appeared in varicella was important. Very often there was no papule, but within a few hours a clear vesicle appeared on the skin. He mentioned a case of scarlet fever which developed chicken-pox.—Mr. A. N. MONTGOMERY said he was pleased to hear that no well revaccinated case had been admitted to the Cork-street Hospital suffering from small-pox. He said that although the vesicle in a revaccinated person might, sometimes on the eighth day, resemble a primary vesicle, yet the material obtained from it should not be used for the purpose of vaccination or revaccination. As showing the necessity of a very careful search for vaccination cicatrices being made in patients suffering from modified small-pox before they were recorded as unvaccinated, he alluded to such a case which had come under his notice some years ago, in which he found a well-marked vaccination cicatrix on the posterior aspect of the arm which had been

overlooked.—The PRESIDENT said that the difficulties of the diagnosis between variola and varicella were perhaps exaggerated. He also said that it was quite well established that the vesicles of chicken-pox were multilocular and were often umbilicated. The greater frequency of umbilication in variola depended on, first, the less acuity of the pathological process, and secondly, because the epithelial cells were cedematous and underwent what was described as a "ballooning degeneration." They became distended and the nuclei were broken up.—Dr. O'CARROLL, in reply to a question, said that several cases of children under ten years of age had been admitted to the Hardwicke Hospital, but that none of the vaccinated ones had died. All the people connected with the hospital had been revaccinated at the commencement of the epidemic, but four months afterwards a laundry maid on whom the vaccination had caused a sore arm was admitted to the wards suffering from a rash he regarded as that of small-pox.

Reviews and Notices of Books.

Colour Vision. Being the Tyndall Lectures delivered in 1894 at the Royal Institution by Captain W. DE W. ABNEY, C.B., D.C.L., F.R.S. With Coloured Plate and numerous Diagrams. London: Sampson Low, Marston, and Co. 1895. pp. 231.

THE work is divided into fifteen chapters, of which the earlier are devoted to a very brief description of the Eye and of the Solar Spectrum, the account of the former referring chiefly to the retina, and of the latter to the circumstances which have led physicists to accept red, green, and violet as probably the three primary colours from which the rest can be formed, and to reject yellow and blue. The experiments of Clerk Maxwell and the hypothesis of Hering are given in some detail, and two chapters are devoted to the Modes of exhibiting Colour Blindness: first, by the spectrum, and secondly, by making mixtures of colours with rapidly rotating colour discs. The results of experiments in regard to some of these matches are very curious. Thus, it is found that both for normal eyes and for colour-blind eyes 118 parts of red with 146 of green and 96 blue give the same grey as results from a mixture of 75 parts of white and 285 parts of black; but in completely green-blind persons the following mixtures gave also the same tint of grey: 251 parts of red and 109 parts of blue were equal to 62 parts of white and 298 of black and 277 green + 83 blue = 107 white + 253 black. Captain Abney then discusses the luminosity of the spectrum in normal and colour-blind persons respectively, and shows that it is subdued in the latter group. The normal yellowish tint of the fovea centralis modifies the sense of colour to some extent, as may be shown by comparing exact matches at the point of fixation with those the images of which fall a few degrees towards the periphery. When the luminosity is gradually reduced the various colours in great measure disappear, a person with normal vision passing through a stage of red-blindness as the intensity is diminished before he arrives at absolutely monochromatic vision. Captain Abney points out that the curious colour of a moonlight landscape is entirely accounted for by this fact. White light becomes greenish-blue as it diminishes in intensity, and the reds and yellows, being reduced or absent, are not reflected by surrounding objects. Hence moonlight is cold, whilst the sunlight is warm owing to their presence. The loss of colours in flowers as night draws on may be easily followed. Thus orange-coloured flowers may be plainly distinguished, whilst a scarlet geranium appears black; green grass will be grey when the colour of yellow flowers may yet be just visible. The eye requires the lapse of a considerable period before it becomes accustomed to darkness and attains its highest degree of sensitiveness, and no experiments on the extinction of light, or rather on the perception of the feeblest amount of light, were found to be satisfactory till after ten

or twelve minutes had passed. In yet another set of experiments Captain Abney determined the distance at which, when cast on a white screen, the different colours of the spectrum of the same luminosity were no longer visible, and found that pure red was invisible at 58 feet, orange 142 feet, green 550 feet, and violet 1000 feet. In accordance with this the reduction of intensity of white light, which when of ordinary brightness is warm, would make it colder, for the red would disappear, and finally the residue of light just before extinction would become a cold grey, due to the absence of all colour. A chapter is devoted to Tobacco Blindness, and the author dwells on the circumstance that such blindness for colour may be the result of excessive consumption of tobacco at any period of life and consequently that those who are entrusted with the care of life through the recognition of coloured signals should be subjected to recurrent examination. The remaining chapters are chiefly devoted to Holmgren's Method of Testing Colour Vision by means of Wools, and to the consideration of Contrast Colours. Captain Abney declines to allow himself to be quoted as a partisan of either of the two rival theories of colour, but on the whole is inclined towards the Young theory. The treatise, brief as it is, may be regarded as supplying an interesting and valuable contribution to the difficult and complicated subject of colour vision. The simple forms of apparatus and general testing he employed in these numerous experiments are depicted, and it is obvious that there is ample scope for further research.

A Compend of General Pathology and Morbid Anatomy. By H. NEWBERRY HALL, Ph.G., M.D. Edinburgh and London: Young J. Pentland. 1894.

It is doubtless difficult to condense within a small compass the salient facts of a wide subject, and for that reason it is incumbent to exercise much discrimination when appraising the value of a book compiled with this intent. Indeed, the whole system of books of this class is open to grave objection, since it is a more or less direct encouragement to the student to rest content with the barest synopsis and does little to excite his interest or his reasoning powers. Nevertheless, such a synopsis drawn up with accuracy and on a definite plan may prove of advantage when used as a supplement to wider studies. The danger is lest it be substituted for the ampler text-book and laboratory guide. As regards the particular compend before us, although it is drawn up on systematic lines and includes a reference to every notable pathological condition, it is certainly lacking in accuracy in some of the descriptive matter. To describe "cancer" as "a system of channels in pre-existing connective tissue filled with continuous columns of epithelial cells," and to state that the "growths are of mesoblastic origin" can hardly be said to represent the teachings of science; whilst it is surely misleading to say that "pernicious anæmia" is a "condition resembling both chlorosis and leukæmia, there being the characteristic changes in the blood of chlorosis, while there is an increase in the number of white blood-cells and the changes in the bone marrow characteristic of leukæmia." Nor can we think the term "fibrous pneumonia" a good substitute for "interstitial" pneumonia. The illustrations are taken from the standard works of Rindfleisch, Billroth, Zeigler, Woodhead, and others.

The Year-Book of Treatment for 1895: a Critical Review for Practitioners of Medicine and Surgery. London: Cassell and Co.

THE eleventh issue of this valuable compilation of knowledge has made its welcome appearance. It is arranged on the same lines as the previous editions—i.e., it is divided into

sections, each section being separately treated by a special contributor. Three new names appear among the contributors to this year's volume: they are those of Dr. Coupland, Mr. Rose, and Dr. Whitelegge. In such a compilation as this book it would be impossible to more than superficially allude to the mass of valuable information which it contains. It is a collection in a readable form of all the chief advances which have been made in the medical world during the past year, thus concentrating a large amount of knowledge which would otherwise be scattered and unattainable by the majority of the medical profession. There is a general spirit of hopefulness imparted through the book which would lead us to believe that great advances are really being made against the diseases which surround us. In the chapter on General Medicine there is an interesting account of the treatment of cardiac disease by exercises and baths which was first introduced at Nauheim, but which has not until quite lately attracted much attention in this country. The tuberculin treatment of phthisis would seem to be flourishing in certain parts. It is said to have been used with success in Egypt, and Barbour of Monteagle, Tenn., is a strong advocate of this treatment, recording its effect upon himself as well as on numerous others; he gives good accounts in many cases, but wisely accords a large amount of credit to the climatic influences the patients were under and to the judicious hygienic and dietetic treatment they were submitted to. An important change in the treatment of Diabetes is taking place by allowing the patients to be on a less restricted diet than formerly. The chapter on Diphtheria is up to date with a full account of the antitoxin treatment, and although leaning largely towards its beneficial effects the author is wisely not dogmatic on the treatment, which may still be said to be in its infancy.

In the division on general surgery there is a good chapter on Surgery of the Spine and Spinal Cord, in which a short summary of Dr. Thorburn's lectures at the Royal College of Surgeons of England is given. There is also an interesting table of cases in which the Gaserian ganglion has been removed. In the department dealing with surgical diseases of children Mr. Edmund Owen believes brighter days to be in store for cases of Acute Intussusception, which at present have such a high fatality. He urges the expediency of considering the case as one for operation from its commencement, and discountenances the treatment by massage, inflation, and injection. By this superficial sketch of the book it will be seen that it is at once interesting and useful, and to the busy practitioner it is invaluable as an aid to keeping up with the times.

ROYAL INSTITUTION.—Lord Rayleigh, F.R.S., Professor of Natural Philosophy in the Royal Institution, will deliver a course of six experimental lectures on Waves and Vibrations, at the institution, on Saturdays, March 2nd, 9th, 16th, 23rd, 30th, and April 6th. The same lecturer will deliver the Friday evening discourse on April 5th, when the appropriate subject will be Argon, the newly discovered Constituent of the Atmosphere.

THE ÆSCULAPIUS LODGE OF FREEMASONS.—An ordinary meeting of the Æsculapius Lodge was held last week at the Café Royal, Regent-street, and notwithstanding the inclement weather there was a good attendance. Mr. Leonard Wilde, M.D. Durh., M.R.C.P. Lond., was admitted to the second degree. Mr. George Herschell, M.D. Lond., was duly proposed as a candidate. The lodge decided to entertain all medical masons that may attend the meeting of the British Medical Association in London in August next; a sum was unanimously voted for that purpose. Dr. G. Danford Thomas generously offered the lodge the use of the Portman Rooms, which offer was accepted.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 23, 1895.

THE annual report of the Local Government Board is becoming more and more bulky as the work of that department goes on increasing, and nothing more than a very summary account of it can be embodied in any ordinary review. Over fifty pages are now taken up with matter relating to county councils and to the Local Government Act of 1894, which is all comparatively new material. Coming next to questions of Poor-law, it appears that during 1893 there was an increase of 4·9 per cent. in the number of paupers as compared with 1892, the actual proportion of paupers being at the rate of 27·6 on every 1000 of the population for England and Wales as a whole; that rate varying in different counties from 45·8 in the agricultural districts of Norfolk to 19·4 in the busy manufacturing districts of Lancashire. At the close of the year guardians did not, with rare exceptions, anticipate any such increase in pauperism as to involve them in any difficulties. The expenditure on the relief of the poor during 1893 amounted to 6s. 3½d. per head of the population, and the cost during the year per head on the mean number of paupers was £12 2s. 11½d., a slight increase on previous years, the increase being mainly as regards in-door paupers. In the metropolis the corresponding amount was £25 8s. 2½d. Dealing next with the concerns of the Metropolitan Asylums Board, it appears that that body is receiving a steady increase in the number of notifications of infectious diseases. In 1891 the total notifications were 20,818 in number; in 1892 they rose to 37,784; and in 1893 they reached 56,425. The admissions to the Board's hospitals during 1893 numbered 18,674.

The year 1893 exhibited an astounding increase in the amounts borrowed with the sanction of the Local Government Board for purposes more or less directly concerned with public health administration. The highest amount hitherto borrowed by urban and rural authorities in any one year was some four millions sterling in 1892, but in 1893 the sum reached £7,266,516, not far from seven millions going to urban authorities alone. And, in addition to this, over four millions were raised by town councils and sanitary authorities under special Acts of Parliament. Local loans thus bid fair, even more than ever, to become a matter of Imperial concern. Already those sanctioned by the Local Government Board alone since 1871 exceed sixty millions. A substantial portion of this account will, however, have been paid off by now. Amongst defaulting authorities some have had to be summarily dealt with. Thus Mill Hill, in the Hendon district, has been required to provide a system of sewers within six months, and Cheam and Cuddington, both in the Epsom rural district, have been somewhat similarly dealt with. Local by-laws continue to be largely approved. In 1893 no less than 504 series of by-laws were made by sanitary authorities. If these authorities only insisted strictly on the terms of their codes being complied

with in such matters as building operations we could feel pretty sure that a golden era was before us in the matter of ordinary dwelling accommodation; but there seems to be no power to require the enforcement of by-laws, neither can the central authority compel authorities to make by-laws. Twenty additional authorities made new regulations with respect to dairies, cowsheds, and milkshops during 1893, a matter as to which we in England have much need to make further progress.

In the matter of the Sale of Food and Drugs Act it appears that during 1893 37,233 articles were submitted to analysis, and of these, 4793, or 12·9 per cent., were found to be adulterated. Spirits take the lead as regards the number of adulterations discovered per cent. of samples examined; next comes milk, 14·9 per cent. of the examples being adulterated; and drugs stand at 11·3 per cent. The question of milk adulteration is discussed at length in the report, and experiments carried out by the authorities at Somerset House show that a number of difficulties have to be contended with. In their experiments the officials always saw the cows milked, and yet milk that was thus genuinely the actual product of presumably healthy cows varied in many important respects. Thus, the total solids ranged from 10·3 to 17·2 per cent. Amongst the other subjects dealt with in the volume are those of vaccination, public health inspections, cholera, and London water-supply. These we shall either deal with separately, or reserve our comments until the issue of the report of the Board's medical officer, in which the several matters are dealt with more in detail.

THE International Congress to be held in Florence next year on the Protection and Management of Childhood is evoking, especially on the Continent, an interest not confined to the societies officially devoted to the subject. The public press, not only lay but medical, is rehearsing the more prominent aspects of the agenda, and already "quite a literature" is being amassed in preliminary discussions on the topics to be taken up. Books even are brought out in anticipation of the Congress, and among these there are some which cannot fail to have a wholesome influence on its deliberations. We may mention the "*Minorenni Delinquenti*" (juvenile delinquents) of the Cavaliere LINO FERRIANI, a distinguished Italian jurist, as covering nearly the whole ground to be occupied by the "Congressisti"; while a place even more authoritative in the same connexion must be given to the address recently delivered in Turin by Professor CESARE LOMBROSO on the "*Dimostrazioni Antropologiche applicante alla Pedagogia*" (Anthropological Demonstration applied to the Upbringing of Youth).

Signor FERRIANI approaches the subject from the forensic and magisterial side, and has much to tell us of the factors, moral and material, which poison the budding human organism on life's threshold. It is in the proletarian that these factors have most unrestricted play, and in which the inevitable results appear in their most significant colours. In the majority of cases the "minorenne delinquente" inherits a more or less absolute want of moral sense, a defect which is aggravated by the vagabondage, the idleness, the hand-to-mouth existence,

and the thousand and one disadvantages in which the "fight for life" in the lowest stratum of society is carried on. Of the 2000 juvenile delinquents who passed under his eye and whose careers, for a time at least, he was able to follow up Signor FERRIANI found the prehensile instincts those in which the vast majority became amenable to the law, crimes of violence, even to the shedding of blood, being next in frequency. Among the youth of the more favoured orders the same proportion between the two classes of offence prevailed, though from causes quite intelligible (the success of parents in hushing up the guilty act, for example) it was found difficult to arrive at anything like certainty as to the amount of criminality existing in that social stratum. Still, where it was detected the etiology was similar, if not identical, depraved organisation, inherited in the first instance and not duly controlled or antagonised in the second, being the *fons et origo mali*.

Crime having its root in psycho-pathological tendencies, conditioned by physical organisation and fostered by early influences or environment, Signor FERRIANI proceeds to review the traditional mode of dealing with it. The penal systems still in force he condemns absolutely, a condemnation coming with all the greater effect from one who does not profess to be a medically-trained anthropologist, but simply a lawyer and magistrate judging from experience. The moral rehabilitation of the "minorenne delinquente" he regards as impossible under the discipline of gaol or reformatory, particularly as practised abroad. The "first offender," after the judicial period served in these establishments, emerges a hardened and thorough-paced desperado, lost to all self-respect and full of vindictive feeling against the society from which he is excluded. Small chance has he of moral recovery or social rehabilitation if relegated back to the parents whose own depravity or culpable negligence drove him, or let him drift, into crime. Nay, Signor FERRIANI'S experience includes many cases in which the parents themselves exaggerate their child's offence so as to procure for him a more exemplary punishment and get him off their hands for a longer period. Either way, the future of the "minorenne delinquente" is the reverse of a hopeful one; and, while Signor FERRIANI cautions us against the roseate colours in which prison governors or penitentiary directors are apt to portray the effects of their discipline, he bids us hope for little improvement in the criminal classes, or in prevention of crime at its source, under any system which does not take account of physical organisation, psycho-pathological tendency, and early upbringing medically inspired.

At this point he practically makes over his case to Professor LOMBROSO, whose discourse—soon, we understand, to be published in a permanent form—attracted one of the largest and most intelligent audiences ever assembled in the sub-Alpine capital. Many of his hearers were school-masters, anxious to gather from him his suggestions as to the best mode of "educating" (not merely "instructing") the youthful mind. His standpoint was throughout the anthropological, illustrated by practical hints as to how to gauge the capacities, the strong faculties and the weak ones, of the young pupil. ANROSSI'S "anthropometer," he showed, could determine with minutely approximate accuracy the proportion constantly existing in normal individuals at successive

periods of life between stature and weight; while the dynamometer could measure the muscular force, and the spirometer give the quantity of air the individual can exhale—the "*capacità vitale*," as he termed it. On the more difficult ground of the cranial capacity he showed how, on the larger or lesser quantity of brain and on its distribution, depends the greater or smaller intelligence of the human subject, and demonstrated by a series of casts how the cerebral weight can be reached through measurement of the cranium itself. But he laid still more stress on the study of the face, from which, by training and experience, the anthropologist can form conceptions of character rarely, if ever, at fault. From the broad outlines of "physiognomic diagnosis," as Professor LAYCOCK used to term it, he proceeded to "facial anomalies," such as are met with in criminals or in moral weaklings—the "mandibole enormi," for instance, the ears like handles (*orecchie ad ansa*), the protruding zygomatics, the "faccia asymmetrica," the strabismus, the lips of exceptional thinness (*assottigliate*), and such like—and pointed out how the criminal is invariably "mancino"—wanting in something—even as a child: be it the sense of colour (*sensu cromatico*) or obtuseness to touch. From an analysis of physiological signs he entered on those in the moral sphere, and illustrated the common defects of juveniles—prone to fibbing (*bugia*), obstinacy, anger pushed to ferocity, overbearingness, idleness, and vanity—all defects which in the "bambino onesto" (morally sound child) disappear with age, while in the "bambino criminale" they remain. It is the latter that the duly qualified educator should separate from the others, so as to prevent the contagion that insensibly deteriorates the sound when associated with the unsound. Were such a sifting process universally practised, by the effective coöperation of the anthropologist with the educator, or by the educator anthropologically trained, the infiltration of society with criminal elements would be checked at its source, while the unsound juvenile would have a chance of being rescued before he drifted into the "minorenne delinquente." Simple moral inculcation, on which "pastors and masters" have hitherto relied for the rehabilitation of peccant youth, Professor LOMBROSO believes to be quite ineffective; but "*la morale pratica*"—the constant example and contagion of good conduct and sound initiative normally carried to healthy issues, such constituting the system of the new or anthropological education—could not fail to build up a generation morally superior to any that had gone before. Professor LOMBROSO, we are told, carried the feeling of his audience with him, and no doubt there is much to be said in favour of such an educational system as that which he has so ably outlined. One thing is certain: that far-reaching reforms must modify the traditional mode of educating youth—particularly proletarian youth—if deterioration, mental as well as physical, is to be obviated at its source. It is upon some such scheme of scholastic reform that debate will principally turn at the approaching International Congress. Finally we note with interest that, while Continental innovation will be directed mainly to the sifting process described by Professor LOMBROSO, the British contribution towards the same end will take the form of combating "over-pressure"—

the exaggeration of that discipline which abroad is found to err in other ways than "excess."

THE Parish Council elections have resulted in several instances in medical practitioners being chosen to occupy seats upon these newly formed bodies, and we welcome the fact, not only as evidence of the confidence and esteem in which our professional brethren are generally held, but also as an omen of good for the success of the new institutions. It is, we believe, in the power of medical men to contribute very largely to this success. There are special reasons for this opinion, for the medical practitioner established in a rural locality possesses qualifications which, speaking generally, may be said to be conspicuously lacking in the case of most of his neighbours. In the first place, he possesses an intimate knowledge of the circumstances of his poorer neighbours such as few among the local gentry can acquire, and he not infrequently enjoys their confidence in a measure that is denied to other residents of his own social position. In this sense he may be said to be one of themselves; but, on the other hand, he is free, as the result of his education and associations, from those prejudices and ties which make it difficult to understand how representative institutions are to take root in rural parishes. The want of initiative and the absence of a habit of coöperation which distinguish the dwellers in the country from the dwellers in the town must seriously impair the efficiency for the purposes of local government of the rural communities and of their representative bodies. Hence the importance of the influence which men trained in the habits of collective action may exercise upon the newly formed councils. They will be able to supply in an eminent degree precisely what is lacking to the parties who, by the new statute, have been forced into a novel partnership. The habits of independent thinking and concerted action, the power of interpreting to the one class the thoughts and feelings of the others, these are the aptitudes for service in this connexion which they may be expected to possess, and these should make their services indispensable to their localities. It is, therefore, matter for congratulation that not a few of our professional brethren have been found willing to assume the burdens of this office, and that their fitness has been promptly and effectively recognised by the new constituencies.

So far, we have dealt only with very general considerations. To the extent already indicated, the medical practitioner will be able to render valuable aid, not less in discussing the lighting of the roads or the diversion of the highways than the questions of sanitation which will claim the attention of the new boards; but it will, of course, be in connexion with matters bearing upon the public health that the benefit of the participation of medical men in the counsels of the parish will be most conspicuous. There are many questions, such as the draining of ponds and the utilisation of water-supplies, which have been specially entrusted to the new bodies. These are matters which in rural districts have a very special importance just because as matters stand at present their importance is but imperfectly recognised. Our village communities have grown accustomed to many seriously insanitary conditions which

would be easily amended if only the requisite criticism were brought to bear upon them and the village intelligence educated to a just appreciation of the inconvenience and risk which such nuisances entail; but for this preliminary process it is indispensable that these things should be regarded from a point of view wholly different from that to which the farmer, the labourer, or the other denizens of the village have grown accustomed. It is fortunate that in reference to such matters the local practitioner will naturally enjoy the prestige of a reputation for exact and scientific knowledge, for there will be no little weight of lethargy and prejudice to be dislodged before such matters as these can be usefully discussed. But, in point of fact, there is room for a very considerable extension of the powers of the parish councils beyond the limits of the matters expressly assigned by the Act to their jurisdiction, for they may receive a large accession of authority by delegation from the district councils appointed under the Public Health Act. These delegated powers have been heretofore exercisable by local committees, but henceforth they will devolve upon the parish councils. If any large use should come to be made of this power of delegation the functions of the parish councils as sanitary authorities may receive an almost unlimited extension and acquire significance quite out of proportion to the modest functions expressly assigned by the Act to the newly created parish authorities. There is thus a new and large demand made upon our professional brethren in rural districts, and we make no doubt that on this, as on many other occasions they will be found by no means wanting in the manifestation of public spirit.

Annotations.

"Ne quid nimis."

SUNDRY QUESTIONS AFFECTING MEDICAL STUDENTS.

NOT the least interesting of the publications of the General Medical Council is the Medical Students Register. The Register for the year 1894 has just appeared, and we may direct the attention of our readers to a few of the principal facts which it brings out. It is very important to know whether the excessive flow of students of medicine continues or not. The Register gathers together into a focus those of every school in the kingdom, and indeed in the empire, and includes, too, a dozen who have passed the examination in preliminary education of certain Continental bodies. In the year 1894 1671 medical students were registered as such. It is curious to notice the examining bodies whose examinations in preliminary education the principal groups of students passed. The University of London heads the list in point of numbers, and it is known to be not behind others in point of severity. No less than 265 medical students, about a sixth of the whole number registered in 1894, had passed the matriculation examination of this University. The next largest group (251) is that registered as passing the examination of the College of Preceptors. The University of Cambridge comes next, and accounts in respect of examination in preliminary education for 199. In Ireland the chief portal of the profession is the matriculation examination of the Royal University of Ireland, on which 102 students registered. In Scotland the examinations in preliminary education of the Universities of Edinburgh, Glasgow, and

Aberdeen had been passed respectively by 83, 93, and 51 of the students registering. The examination in Arts of the Apothecaries' Society was passed by 70 students who registered. Of non-medical bodies, the Educational Institute of Scotland ranks next in numbers to the College of Preceptors, having passed 95. Another table gives the places of medical study whereat the students registered commenced their work. Here the University of Edinburgh has the lead with 154 students but is very closely followed by the University of Cambridge with 153. The University of Glasgow follows with 96. Coming to the strictly medical schools, the greatest number of students—86 in 1894—commenced work at Guy's Hospital, at Owens College 66, and at St. Bartholomew's Hospital 65. The largest numbers in Ireland were in the Catholic University Medical School, Dublin, which had 50 entries, followed by 40 at Queen's College, Belfast. At the foot of p. 11 a note informs the reader that pupillage is no longer valid as a commencement of professional study. By a recent resolution of the Council registration as a student can only be effected on commencement at a university, a school of medicine, or a teaching institution, where physics, chemistry, and elementary biology are taught, recognised by a licensing body. Pupillage to the extent of six months is recognised by the General Medical Council, but at the other end of medical education—in the fifth year. A very important question, How does the whole number of commencing students compare with that of previous years? is answered by a table on p. 12. This shows 78 less than the previous year, but exactly the same number as in the year 1892. A valuable table gives the registration of students annually from 1865 to 1894. The average annual entry for the last ten years has been 1901. It is too soon to conclude that there is any adequate perception of the crowded state of the profession, but it is something to have had in two recent years an entry of 230 below the average of ten years. It appears that of 47,930 students registered in the three divisions of the kingdom in the twenty-nine years 23,906 (49.88 per cent.) were registered in England, 14,526 (30.30 per cent.) in Scotland, and 9498 (or 19.82 per cent.) in Ireland.

THE DANGERS OF STREET PENNY TOYS: A PROTEST.

FAR be from us the wish to add to the lamentably well-filled ranks of the unemployed, or to prevent any man from earning a more or less honest living. But he who would live must also let live, and not, as too often in the case of the street seller of penny toys, imperil the lives of others. We have often alluded to this very real danger. Our present protest is impelled by personal ocular demonstration. Beneath our windows stands an honest son of toil—who, to make a rough and ready diagnosis from inspection, is a veritable culture ground of tubercle bacilli and a fit subject for the hospitality of a hospital, "consumption" or otherwise—persistently and as energetically as his lungs will allow imitating the warblings of the feathered songsters who do not inhabit the Strand by blowing down the spout of an apparently rather pretty little imitation of a milk jug, numbers of which he carries on a tray. Unconsciously, no doubt, he makes his little effort towards antiseptics by transferring from a tin box to his mouth from time to time a portion of tobacco of Cimmerian hue. The disinfecting properties of tobacco are as yet not clearly proved—at all events as regards the bacillus of tubercle. The filthiness of the procedure is, in the present instance, undoubted, and will, we trust, when we make it known, act as a potent prophylactic by preventing people purchasing these dangerous toys. Another street vendor perambulates a limited

portion of pavement offering for sale what appears to be a grotesque doll of pantomimic aspect, whose head requires to be kept at hydrocephalic proportions by constant expirations from the lungs of its peripatetic proprietor. He happily presents no apparent signs of tuberculosis, but, alas, there is the possibility of other and even worse contagious diseases to be considered, not necessarily in him as an individual, but in his numerous *confrères* plying their trade along some miles of London thoroughfares. Let it be well taken to heart that these penny toys must be bought by a great number of persons and taken home to their children, a large proportion of whom may possess a "soil" richly prepared by heredity to receive and fructify the seeds of tuberculosis. Let the other horrible possibilities of the transference of disease be borne in mind, and it will be recognised that this is no mere passing "scare" that we raise, but a most serious danger to the health of the community worthy of the earnest attention of our legislators, engaged though they are with other matters of pressing importance. Trade such as this requires legal supervision. At any rate the element of personal infection should be discouraged. The possibilities of scarlet or other fevers from the housing of these wares at night are bad enough; the certainty of direct microbic infection is appalling.

THE BUDAPEST CONGRESS AND THE DRINK QUESTION.

It will take a considerable time before the official report of the Eighth International Congress of Hygiene and Demography, which met at Budapest last September, can be published. Indeed, considering the enormous number of subjects treated and papers read, the issue of anything like a complete report is a most formidable undertaking. In the meanwhile, the text of the resolutions carried has been issued in pamphlet form and in four languages, Magyar, French, German, and English. The moral value of these resolutions rests principally in the fact that they were adopted by the Sections in which they were discussed. As explained by our special correspondents who attended the Congress, the general meeting of the entire Congress which should have confirmed or rejected the resolutions carried in the Sections was a dismal failure. Though as many as 2500 persons were inscribed as members of the Congress there were never more than 120 persons present at the general meeting, and much of the work was done when only forty or so remained in the room. The resolutions accepted by this poorly attended general meeting were read out at the official closing ceremony of the Congress, where a far larger number of persons was present. But these resolutions were then read as a matter of form, and no discussion was either possible or attempted. For the most part they were described in the columns of THE LANCET at the time; but there are some few subjects which, from plethora of material, were omitted or but briefly mentioned by our correspondents. Among these we would mention the vexed question of alcoholism. Now that the Government of Great Britain is pledged to legislation on the liquor traffic it may be useful to see what resolutions were adopted on the subject by the last International Congress of Hygiene. In the Fourth Section a resolution proposed by Dr. Béla Axmann was carried, and it was confirmed at the subsequent general meetings of the Congress. It was to the following effect: "Considering that 61 per cent. [presumably in Austria] of the accidents happening in factories and workshops are caused by the use of alcoholic drinks, the attention of the Governments ought to be called to this fact. The Section proposes that the price of light beverages such as beer, which are less harmful, should be lowered as far as possible, whilst that of strong intoxicants should be raised

high enough to render their consumption more difficult." Again, in the Fourteenth Section, a resolution brought forward by Drs. Crocq, Witlaçil, and Eulenburg was adopted and confirmed by the general assemblies. It is thus worded: "The public authorities should be requested to combat the abuse of alcohol according to their position with all their power. The means for this end are the following—viz., temperance and abstinence associations; restriction of the sale of alcoholic liquors, especially that of brandy [presumably spirits generally]; supervision of the manufacture of brandy and assumption by the State of its monopoly; raising of the taxes on spirits and brandy, and lowering of the taxes on wine and beer; and establishing asylums for drunkards and placing habitual drunkards under legal guardianship." Professor Aglave, Doctor in Law of the Paris University, is in a great measure responsible for the above resolution. For many years he has travelled from country to country interviewing members of various Governments, and collecting a large amount of evidence for the purpose of proving that the best way of combating alcoholism is to ensure the sale of absolutely pure—that is to say, sufficiently rectified—alcohol, and that this result can only be attained by making the manufacture and sale of alcohol a State monopoly. The Swiss and the Russian Governments have already adopted this proposal, and there is, we believe, some prospect that the French Government will follow suit; while in Canada the Dominion Government exercises an absolute control over the manufacture and storing of alcohol.

THE RED CROSS IN ABYSSINIA.

WHETHER, or to what extent, the recent successes of the Italians on the Abyssinian frontier will encourage Signor Crispi in his African policy, and lead to the consolidation of that "Colonia Eritrea" which for the last ten years has been a burning question in Italy, is one of the interesting problems of the immediate future—interesting, indeed, to several other European Powers than the Italian, and not least so to our own. Meanwhile there is one cause which already sees an opportunity for development in those semi-civilised regions, and that is the Red Cross organisation. Of late years the European Powers have been engaged in a series of those "little wars" which in the Duke of Wellington's opinion are more costly than advantageous, but a redeeming feature of which is the extended usefulness they have given to the "care and cure of the wounded in battle." The conflict between Spain and Morocco brought back to life that Spanish Association of the Red Cross which had fallen into desuetude since the Carlist rising some thirty years ago, and now the campaign of General Baratieri on the Italo-Ethiopic frontier has aroused the "Croce Rossa Italiana" to seek a fresh field for its energies in the far east of the same continent. France and Belgium have already, in their respective "spheres of influence," awoken to their responsibilities in that direction, till we may fairly look forward, before the century closes to the establishment of as many centres of the Red Cross organisation as there are European nationalities effecting a foothold in "Darkest Africa." As becomes the Power which claims priority in the humanitarian idea which was embodied in the Geneva Convention, Italy has lost no time in making the extension of her military operations to the Soudan coincident with a transference of her Red Cross material and *personnel* to that region, and, with the coöperation of her War Office, she is organising throughout the more vulnerable tracts of the "Colonia Eritrea" a series of ambulance stations on the model of those which, of late years, have given so good an account of themselves in the autumn manœuvres of her army in the Alta Italia. In the hill country of Asmara, already utilised as summer quarters for the garrison at Massowah, she contemplates a convalescent

sanatorium in supplement to those frontier stations, and this may be regarded as the prelude to the opening up of that delightfully salubrious region to the service of other patients than those drawn from the army. Civilisation, indeed, has everything to gain in tracts stretching inland from the Red Sea littoral by the planting of hospitals and health resorts on the European model, and the energy with which the Italian initiative is being taken towards that end must act as a wholesome stimulus to other Powers whose colonial interests in the same continent are at once more extended and more menaced. The "Prefettura Apostolica," which, in coöperation with the Vatican, Signor Crispi has established in the Tigre and throughout the "sphere of Italian influence," is fitly followed by a "Prefettura Igienica"; and this, both for the work it is capable of doing and the example it holds out to other Powers similarly circumstanced on the same continent, will go far to reconcile the votaries of "peace at any price" to that forward movement in Africa to which, by the *force majeure* of competition and the need of Europe for an expansion of her "colonial outlet," nearly all the more enterprising nationalities see themselves inexorably committed.

IS IT INFLUENZA?

THE word "influenza" is rapidly approaching the status of Abracadabra or "that blessed word Mesopotamia," or the Ægean Sea, which latter was always the refuge of the school-boy geographer. Nor can we wonder at this when we remember the protean forms in which the disease did undoubtedly manifest itself from 1889 to 1892. At the present time there is certainly a widespread catarrhal affection of some kind which is generally called "influenza," though we rather doubt whether it always is. By influenza we mean an acute febrile attack, the incubation being very short and the onset of the disease being characterised by severe muscular aching, a rigor, a high temperature and intense headache, and sometimes vomiting and diarrhoea. All or most of these symptoms pass off in twenty-four to thirty-six hours, leaving the patient greatly prostrated and with a troublesome cough and some bronchial catarrh; but though there are certainly some sporadic cases of influenza about, we would issue a warning against the growing habit of calling every indefinite feverish attack by this name. That it is a temptation no one will deny, especially when we consider how anxious patients are that their disease should be named and how the practitioner is apt to be looked down upon if he says he cannot do so. But it must also be remembered that influenza is a serious disease, and it is therefore unwise to call any febrile catarrhal affection by this name, for these latter when properly treated never leave any serious sequelæ, whereas the former complaint, even though treated with every care, may, and often does, leave a large legacy of grave evils behind it.

RATIONAL DRESS.

AMONG the many definitions of man is one which defines him as the only animal that wears clothes. Now this would be correct if we added the word vertebrate, for several of the lower animals do wear clothes, and wear them, too, with a sense of their fitness and sensible use that puts the bimanous vertebrate to shame. Among these animals who have solved the problem of rational dress are the hermit crab, the larva of the caddis, and certain caterpillars. These clothes are rational in so far that they are fitting for whatever the wearers are doing (of course the problem is simplified when the day's occupation consists of little else than eating and sleeping); but how far below these creatures in our use of dress are we. Men have for ages scoffed at women for the vagaries and flights of fancy displayed in their dress, but there is really but little to choose between the sexes

except in the great matter of the pocket, for except a professional thief no mortal being, even the owner, can get at a woman's pocket. It is more, however, the weak points of men's dress to which we desire to draw attention, and specially to the fact that the lungs, as far as anatomy goes, are exposed at the back almost more than at the front. Yet man's clothing overlooks this fact. A man's shirt is at least three times thicker in front than at the back, his waistcoat is always a mere lining at the back, and if, as the majority of men do, he does not button his coat his back is sure to be much exposed. Take again the change from morning to night. During the day a man goes about with thick woollen clothes, thick socks, thick boots or shoes with spats. At night he puts on very thin clothes, a waistcoat which is no protection whatever, thin shoes, silk socks, without any spats, and sallies forth to dine, after which perhaps a dance or a theatre. When arrived he congratulates himself that he is not as those poor silly women who go about with the upper part of their chests bare. We are certain, however, that men catch cold from wearing evening dress far more than women do, and it behoves all who go out in the evening to keep the legs and feet warm as well as the upper part of the body, and to wear an extra vest to make up for the practical disappearance of the waistcoat.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

We would direct the attention of the governors and treasurers of the various hospitals and dispensaries of the metropolis, who desire that their institutions shall participate in this year's distribution, to the necessity for sending in their applications to the Secretary of the Fund, Mr. H. N. Cunstane, at the Mansion House, on or before March 5th. Applications must be accompanied by the income and expenditure account for the past year, printed according to the uniform system agreed upon and duly audited by a public accountant. The addition to Law IV. of the Constitution which came into force on Jan. 1st, 1893, making it compulsory that the accounts of each institution should be presented on a uniform basis, has greatly facilitated the labours of the Distribution Committee in comparing the relative merits of the respective institutions, and unless this rule is complied with no award will be made. We regret to have to call attention to a practice which cannot be too severely condemned—namely, that of issuing one report to the Hospital Sunday Fund satisfying these requirements and another to the supporters of the institution concerned. Such proceedings are not calculated to increase public confidence, and, it is hardly necessary to say, will not be recognised by the Distribution Committee, who require one form of account only. We regret that we should have to refer to this matter, and trust that Sir Sydney Waterlow—who we hope will be permanently restored to health and be able to move, as he has done for twenty-two years in succession, the adoption of the Distribution Committee's report this year—will not, as he did on the previous occasion, have to deplore such proceedings.

OPHTHALMOPLÉGIA AND WEAKNESS OF THE OCULO-FACIAL GROUP.

SINCE the experiments carried out by Mendel showing that in certain animals the orbicularis palpebrarum seems to receive its nerve-supply from the third cranial nerve nucleus a few noteworthy observations on the subject in man have been recorded. Drs. Tooth and Turner, in a valuable account of a case of bulbar paralysis, found that while the cells of the facial nucleus were completely degenerated the nerve itself had in it undegenerated fibres, and they thought that these were probably derived from the third nucleus and were for the supply of the orbicularis palpebrarum and frontalis, which had been found

functionally active during life. Dr. Hughlings Jackson has also recorded in the columns of THE LANCET his observations on cases of ophthalmoplegia, in which he found that when the eyes were as tightly closed as possible there was no difficulty, or comparatively little difficulty, in raising the upper eyelid. The other facial muscles being intact this weakness of the orbicularis was naturally regarded as a result of the impairment of the third nucleus, which presumably had led to the paralysis of ocular movements. Such an observation naturally lent considerable support to Mendel's hypothesis that the third nucleus supplied the nerve filaments to the orbicularis palpebrarum, just as the hypoglossal nucleus is supposed to be the source of the nerve fibres which supply the orbicularis oris. There can be no doubt that functionally the ocular movements and those of the orbicularis palpebrarum are very closely associated, just as those of the tongue and of the orbicularis oris are. In a recent number of the *Wiener Klinische Wochenschrift* Dr. Hanke records a case of congenital ophthalmoplegia, or of ophthalmoplegia occurring in very early life and affecting nearly all the ocular muscles of both eyes, in which in the twenty-sixth year of life a paralysis of the levator palpebralis superioris and also of the frontalis took place. The case, according to Dr. Hanke, supports Mendel's hypothesis that the oculo-facial group is supplied by the third nerve nucleus.

INTERNATIONAL CONGRESS FOR THE PROTECTION OF INFANCY.

WE announced in THE LANCET of Dec. 15th, 1894, that Florence would, within the coming year, be the seat of the International Congress for the Protection of Infancy, and we indicated the quarter from which its *personnel* would be most largely recruited, as also the tenour of the discussions, so far, at least, as the communications sent in enabled us to judge. Since then, however, the Italian organising committee, which has its headquarters in Florence (No. 7, Piazza d'Azeglio), has had intimation that another congress with the same object and on the same lines to be held in 1895 has been preparing in France, and so, to obviate the inconvenience of two such meetings occurring within the same twelvemonth, it defers its own meeting till the October of 1896. This is as it should be, and the loyalty with which the two committees are coöperating gives promise of a highly effective promotion of the interests both have at heart. The French Congress will meet at Bordeaux on Aug. 12th, and its work is divided into three principal sections. The first takes cognisance of Children Morally Abandoned, and will deal with the Decline of Parental Authority and the Delegation of this latter to other Hands. The second has for its main subject the Administrative Protection of Infancy. It will take up the well-known "Loi Roussel," which has aided considerably in diminishing the death-rate among children put out to nurse. The application of this law and its further extension to all children reared, gratuitously or not, outside the parental roof will form the theme of many important papers and discussions. The third section will concern itself principally with the Physical Protection of Infancy, under which head the question of the alimentation of the child from his first day of life to the close of its second year will be threshed out in all its ramifications. An elaborate monograph has been announced on the Means to be employed by Private Initiative to secure the soundest Methods of such Alimentation, the author's name being as yet withheld. From the programme now before us the Congress cannot fail to be an effective one, the Italian contingent having thrown itself with zeal into its proceedings; while there is every probability that the misguided patriotism which kept

France from being represented at the Tenth International Congress of Medicine and Surgery, which met in 1890 at Berlin, will arouse no German reprisals with regard to the meeting to be held at Bordeaux. French hospitality may be trusted to treat the delegates from the Fatherland with all courtesy and consideration, in harmony with the philanthropic motive which brings the Congress together. We may add that the provisions for the comfort and entertainment of the delegates from abroad are commendably liberal—*inter alia*, the entrance ticket being presented gratuitously to each on his announcing himself in Bordeaux.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

In the report of the London and Counties Medical Protection Society, Limited, for 1894, which we have just received, are some very interesting accounts of cases in which action has been taken by the society. The report refers to the Indian oculists prosecution, which has already been commented upon in our columns,¹ and expresses a hope that although the trial of 1893 did not end in a conviction it may lead to an amendment of the Medical Acts. Several instances are given of the successful prosecution of unqualified practitioners, and as regards the case of Mr. Anderson of Tobago the report intimates that it must be carried before the highest appellate tribunal in the realm. A short account of the abortive attempt at amalgamation with the Medical Defence Union is given, from which it would seem that at present there is not much hope of union.

THE DIFFUSION OF SMALL-POX.

THE fresh cases of small-pox in London were last week 8 in number, against 11 in the preceding week, and there was 1 registered death, that of an unvaccinated person belonging to the parish of Marylebone. Some anxiety has been caused in that parish owing to recent events in connexion with the occurrence of unremoved cases of small-pox. One house in the locality of Lisson-grove was the residence for ten days of a malignant case of small-pox, which proved fatal within a few hours of diagnosis and notification. During the next fourteen days fully a score of fresh cases arose in the parish which could be traced with certainty or great probability to infection derived at the house in question, occupied as it was by five families. Great activity has been manifested in dealing with the evil results of this case; but anxiety is not yet at an end, inasmuch as at least 3 additional cases have come to light after varying intervals of residence of unremoved small-pox patients in the midst of other susceptible persons, and mischief may, it is feared, yet result from these occurrences. We are glad to learn that the vestry have resolved to erect a shelter and baths for the use of persons who have been exposed to the danger of contracting infectious diseases, together with means for the disinfection of their clothing. In West Ham, where in the first week of February small-pox showed serious recrudescence, only 2 attacks were chronicled last week. At Birmingham, too, the attacks fell to half the previous week's record, only 6 being noted last week, with 1 registered death. At Liverpool and Bootle we hear of a dozen attacks. The Registrar-General for Scotland returns 8 deaths from small-pox in the great towns during January—namely, 2 in Glasgow, 5 in Edinburgh, and 1 in Leith. In Dublin there were admitted to hospital in the week ended Feb. 9th 60 small-pox cases, as compared with 61, 64, and 69 in the three preceding weeks, the discharges numbering 84 and the number remaining under treatment being 141, in addition to 142 convalescents at Kilmalham, or 283 in all. Seven deaths from small-pox

in the week occurred, 2 in vaccinated adults and 5 in unvaccinated persons, one a child aged five and the rest in adult life. Of the 68 persons dying from small-pox in Dublin in 1894, all in the last six months of the year, as many as 39 were unvaccinated; all the 16 children under five years of age dying from the disease belonged to that class.

ENDOCARDIAL LESIONS IN TUBERCULOUS SUBJECTS.

THE effects of endocardial lesions on the course of tuberculosis is an old and well-discussed subject, but in the *Annales de Médecine* of Feb. 8th we find it dealt with from rather the opposite standpoint—i.e., the effect of tuberculosis on diseases of the endocardium. The conclusions there given are those arrived at by Telsier in his work on the subject. Endocardial lesions due to tuberculosis are multiple in form and complex in pathology, the tubercle bacilli, toxins, and associated bacteria all combining to produce the disease. The bacillus acts locally by producing a specific lesion, and generally by its deteriorating effect on nutrition. The tubercule, on the other hand, is said to influence the vaso-motor system and so to be specially active in the sclerosing forms. The specific lesion showing itself as granular or caseating nodules is rare, being less frequent than tuberculous pericarditis. It is always a secondary lesion due to presence of bacilli in the circulation, and does not cause any characteristic cardiac signs. The sclerosing form is frequent and the result of slow tuberculous infection. It occurs in the course of chronic tuberculous cases, and shows itself by producing harsh cardiac murmurs. Many of the cases of valvular disease in scrofulous subjects are thought to be influenced by the presence of tuberculous toxins. An acute form due to secondary infection is also described, which appears to tally by its clinical course with infective endocarditis. It may, like infective endocarditis, take a vegetative or an ulcerative form, but more work has yet to be done before accurate conclusions can be drawn.

INSANITY AMONG THE NATIVES OF SOUTH AFRICA.

IN the January number of the *Journal of Mental Science* Dr. Duncan Greenlees, the Medical Superintendent of the Grahamstown Asylum, South Africa, has a very interesting paper on this subject. He has gone over the cases of natives admitted to the asylum in the last nineteen years, and has classified his results under several headings. In regard to age he finds that in males the most frequent age is between twenty-five and thirty years, while in females it is thirty to thirty-five years. By far the most common form of insanity is mania, melancholia being rare, and in the acute form in which it is found among white patients extremely uncommon. Epilepsy and epileptic insanity are not unknown among native races, even apart from traumatic cases, but general paralysis is so rare that amongst the pure natives it may be considered not to exist. It is difficult to get at the causes of insanity among natives, the history being, of course, necessarily imperfect. But Dr. Greenlees mentions two important causes—viz., excessive drinking of alcoholic beverages and the smoking of *dagga*, a plant almost identical, it is said, with Indian hemp, which produces temporary intoxication, ending sometimes in an outburst of maniacal excitement. As to the causes of death, the frequency with which chest diseases are the immediate cause is noteworthy, and also the rarity of actual gross brain disease as a cause. This last fact is probably explained by the absence of conditions of life likely to cause cerebral disease, while the former seems to indicate that the clothing of the native, with the liability to sit in wet clothes, &c., renders him liable to pulmonary affections.

¹ THE LANCET, Nov. 4th, 1893.

As to the nationality of the natives treated the great majority were Kaffirs and Hottentots, the two native races most closely associated with the white, and therefore presumably exposed to more nearly similar conditions than other natives would be living remote from civilisation and the deteriorating influences which the white man seems to carry with him to native races.

CLINICAL SOCIETY OF LONDON.

THE Council of the Clinical Society has unanimously resolved that, owing to the death of the late President, Mr. Hulke, F.R.S., the meeting arranged for Friday, Feb. 22nd, will be postponed to Friday, March 1st, at 8.30 P.M. The agenda will be the same as originally announced in THE LANCET of the 16th inst.

THE MEDICAL REGISTER.

THROUGH the courtesy of Mr. W. J. Miller, the Registrar to the General Medical Council, we have received a copy of the Medical Register for 1895. At the end of last year the total number of names on the Register was 32,637; at the end of 1893 the numbers were 31,644. If we mistake not the Register makes its appearance earlier this year—a fact upon which we congratulate Mr. Miller.

MORVAN'S DISEASE AND LEPROSY.

AS is well known some writers assert that not only Morvan's disease but also scleroderma and Raynaud's disease are merely varieties of leprosy. The position of the question has been considered by M. Gombault in the *Revue Neurologique*.¹ He asks if it would not be more prudent and at the same time more scientific to consider this as a hypothesis, seductive and fascinating no doubt, but still awaiting proof. M. Marestang, he says, has examined the question from the clinical point of view, and finds that even in this respect Morvan's disease and leprosy are by no means identical. Moreover, pathological anatomy does not furnish any confirmation of the view, for neither has the bacillus of Hansen been demonstrated in any of the cases of Morvan's disease examined by M. Gombault, nor have the changes in the peripheral nerves been found which are characteristic of leprosy; and as to the spinal cord this has only been twice examined in cases occurring in Brittany, and in both this organ was manifestly the seat of syringo-myelia—a condition which is in all likelihood the anatomical substratum in cases of Morvan's disease. This, of course, does not imply that cases of leprosy may not have symptoms closely analogous to those found in certain cases of Morvan's disease, but to acknowledge this and to claim that the diseases are identical are two very different things. Their identity could only be established by the demonstration of the bacillus of leprosy in an acknowledged case of Morvan's disease.

MIDWIVES AND THE DEATHS OF CHILDREN.

AN inquest was held at Woking recently by Mr. G. F. Roumieu, coroner for West Surrey, on two children aged two months and six weeks respectively, who both died from pneumonia attributed by the medical witness, Mr. Howlin, to blood poisoning produced by the midwife using her own appliances. The chief evidence in support of this view was the death of the two children within so short a time attended by the same midwife, who, instead of using materials and instruments supplied by the parent, is said to have used her own. Theoretically, of course, if midwives were well trained their instruments and materials should be safer than those of others. The midwife said she always disinfected her instruments with carbolic acid. And it

must be allowed that in a season of intense frost the occurrence of two cases of pneumonia is not in itself necessarily proof of fault in the nurse. But the coroner and the jury and Dr. Seaton, medical officer of health of the County Council of Surrey, and Mr. Wellington Lake, medical officer to the Guildford sanitary authority, all seemed to concur in the theory which traced the pneumonia to blood poisoning and not to cold. Dr. Seaton thought that such cases should be notified. All agreed that the midwife, Mrs. Lee, bore a good reputation, and the coroner said she left the court without any stain on her character. She said that between these two cases she had attended ten others without anything wrong occurring in the children. Dr. Seaton and Mr. Lake promised to draw up rules for the guidance of this midwife in future. Certainly midwives cannot be too particular in cleansing and disinfecting their hands, instruments, and clothing.

BACTERIOLOGY OF CHOLERA.

AS the result of some careful and extended observations upon cholera patients made at the Hygienic Institute of Königsberg, Drs. R. Abel and R. Clausen conclude¹ that : 1. Cholera vibrios in faecal matter as a rule die within the first twenty days; they seldom remain alive for thirty days; whilst the prolongation of their existence to fifty-two days, as has been noted by Karlinski and Dunbar, is quite exceptional. 2. In many stools cholera vibrios cannot be found after from one to three days; hence the necessity of examining the dejecta of cholera patients as soon as possible after they have been passed. In an appendix to this paper it is shown that cholera vibrios may occur in healthy individuals, and it is urged that isolation should not be discontinued until repeated bacteriological examinations have proved the bacilli to be absent. They give particulars of seventeen individuals, members of families in which cholera had occurred in Wehlau (Eastern Prussia) in the autumn of 1894. Of these seventeen persons, who did not sicken or only had slight transient diarrhoea, examination of the stools showed an exceptionally large percentage of cholera vibrios. In many cases, however, one or more days would elapse before any organisms were detected, and then they would again appear in abundance, showing that if the patients had been allowed out of quarantine on the first occasion that the stools were found to be free from bacilli they might have disseminated the disease. In one case it was possible to determine with fair accuracy the incubation period of cholera. This was the case of a man, a member of one of the infected families, whose stools daily examined yielded no bacilli; an examination on Oct. 1st of a stool passed on Sept. 30th yielded a like negative result, but he was attacked with cholera in the night of Sept. 30th—Oct. 1st, and died on the 2nd. Hence it is inferred that the time between infection and onset of symptoms in this case must have been between twelve and twenty-four hours.

DR. CURNOW will take the chair at the King's College Hospital past and present students' dinner, which is to be held at the Holborn Restaurant on Friday, March 1st. Any past students who wish to be present should apply for tickets at once to Messrs. J. Gott and A. H. Safford at the hospital.

A DISCUSSION is announced to take place on Tuesday evening next at the Royal Medical and Chirurgical Society upon Affections of the Nervous System occurring in the Early (Secondary) Stages of Syphilis.

SIR RICHARD QUAIN has accepted the office of President of the North-West London Clinical Society.

¹ Archives de Neurologie, January, 1895.

¹ Centralblatt für Bakteriologie, 1895, Nos. 3 and 4.

PROFESSOR CLIFFORD ALLBUTT will give a lecture before the Hunterian Society on Wednesday, Feb. 27th, at 8.30 P.M., in the London Institution, Finsbury-circus. He has chosen for his subject Senile Plethora: High Arterial Tension in the Aged. All members of the profession are invited.

ARMY MEDICAL DEPARTMENT REPORT FOR 1893, WITH APPENDIX.

[FIRST NOTICE.]

THE medical report on the health and sanitary condition of the army for 1893, making the thirty-fifth volume of these reports, which has just been issued, consists with its appendices of 397 pages. In the latter are included some interesting papers and reports, such as those on the Progress of Hygiene for 1894, and on the late International Congress at Budapest for the same year, by the Professor of Military Hygiene at Netley; a list of operations at Netley by the Professor and Assistant-Professor of the Army Medical School; a report on the Eighth Congress of the Association Française de Chirurgie, by Surgeon-Lieutenant-Colonel Pratt, and one by Surgeon-Major H. E. R. James, F.R.C.S. Eng., on the Late Epidemic of Bubonic Plague at Hong-Kong, together with papers by different members of the Army Medical Staff descriptive of surgical and other cases that have come under their observation or treatment.

The major portion of the volume, consisting of the official report on the health of the troops at home and abroad during 1893, gives the usual statistical data, tables, and summaries, with the necessary descriptive or explanatory comments and brief references to disease causes and sanitary conditions with which our readers are familiar.

The prefatory observations to the present volume sum up the general results so succinctly and well that we cannot do better than follow them pretty closely. The health statistics of the troops at home for the year under review are favourable. A serious outbreak of enteric fever occurred at Aldershot. Influenza was largely prevalent in 1893, but not quite to the same extent as in 1892. For all forms of venereal affection there was a slight decrease in the admission-rate, but a fractional increase in the constantly-sick rate. There is no other matter, it is stated, calling for special notice in regard to the health of the troops serving in the United Kingdom in 1893.

As regards the colonies, some of the notable points referred to are: the admission-rate at Gibraltar was higher than in 1892 owing to the prevalence of simple continued fever, and the sick-rate for venereal affections showed a considerable increase. At Malta there was an outbreak of enteric fever attributed to contaminated water. In Canada the health of the troops was excellent. Enteric fever was rather prevalent in Bermuda. Malarial fever of a severe and fatal type was very prevalent in the Mauritius in 1893, and it is remarked that residence there is either followed by an increased liability to this form of fever or by a general deterioration of health. In China, as in the Mauritius, much of the bad health of the troops was also attributable to the same cause—malarial fever. In Egypt, as at Cyprus and in the Barbadoes command, the chief cause of inefficiency is stated to have been venereal affections, nearly a third of the admissions to hospital having been due to these diseases. In India the health of the troops was fairly good. The increased prevalence of venereal affections in the three Presidencies is referred to. In Bengal enteric fever was not so prevalent in 1893, and cholera showed a marked decline; in Bombay the health of the troops was very good; and there was no special outbreak of sickness to be recorded among the troops in Madras in that year.

Turning to the statistical summaries shown in the tables on the second and third pages of the report, we find that the average strength of the troops at home and abroad was 202,125, and that 100,105 of this number were stationed in the United Kingdom and 69,865 in India, the remainder being distributed throughout the various other commands, and notably those of the Mediterranean. The hospital admission-rate of the troops at home and abroad for 1893 was 1010 5, the death-rate 8.30, and the number sent home as invalids was 24.21, of whom 13.30 were discharged as invalids, per 1000 respectively; the constantly non-effective from sickness was

60.90 and the average duration of each case of sickness was 22.01 days per 1000. The death-rate in the United Kingdom was 5.13 per 1000, at Gibraltar it was 2.74, in Cyprus 1.82, and in Canada 2.11; while at Malta it was 10.47 per 1000, in Egypt 13.60, in the Mauritius 18.14, and in India 13.15 per 1000 respectively.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6906 births and 5430 deaths were registered during the week ending Feb. 16th. The annual rate of mortality in these towns, which had risen in the three preceding weeks from 18.7 to 20.7 per 1000, further increased last week to 26.7. In London the rate was 29.3 per 1000, while it averaged 24.9 in the thirty-two provincial towns. The lowest rates in these towns were 14.5 in Croydon, 18.3 in Hull, 18.7 in Plymouth, and 19.8 in Derby; the highest rates were 27.2 in Manchester, 27.3 in Preston, 27.7 in Leeds, 29.2 in London, and 39.6 in Liverpool. The 5430 deaths included 315 which were referred to the principal symtotic diseases, against 297, and 312 in the two preceding weeks; of these, 93 resulted from whooping-cough, 64 from measles, 52 from diphtheria, 36 from scarlet fever, 35 from "fever" (principally enteric), 33 from diarrhoea, and 2 from small-pox. No fatal case of any of these diseases was recorded in Huddersfield or in Hull; in the other towns they caused the lowest death-rates in Brighton, Croydon, Nottingham, and Preston, and the highest rates in Wolverhampton, Sheffield, Manchester, and Burnley. The greatest mortality from measles occurred in Sheffield, Gateshead, and Plymouth; from scarlet fever in Burnley; from whooping-cough in Bristol, Norwich, and Birkenhead; and from "fever" in Bolton. The 52 deaths from diphtheria included 27 in London, 4 in Liverpool, 3 in Wolverhampton, and 3 in Birmingham. One fatal case of small-pox was registered in London and 1 in Birmingham, but not one in any other of the thirty-three towns. There were 67 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 16th inst., against 35, 58, and 56 at the end of the three preceding weeks; 18 new cases were admitted during the week, against 8, 21, and 18 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1657, against 1662, 1653, and 1667 on the three preceding Saturdays; 159 new cases were admitted during the week, against 186, 160, and 149 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 324 to 480 in the three preceding weeks, further rose to 840 last week, and exceeded by 382 the corrected average. The causes of 131, or 2.4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Oldham, Leeds, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Huddersfield, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23.9 and 26.2 per 1000 in the two preceding weeks, further rose to 35.1 during the week ending Feb. 16th, and was 8.4 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 20.6 in Perth and 22.1 in Leith to 41.9 in Greenock and 43.0 in Glasgow. The 1013 deaths in these towns included 46 which were referred to measles, 33 to whooping-cough, 17 to diarrhoea, 6 to scarlet fever, 6 to diphtheria, 6 to "fever," and one to small-pox. In all, 115 deaths resulted from these principal symtotic diseases, against 89 and 81 in the two preceding weeks. These 115 deaths were equal to an annual rate of 4.0 per 1000, which was 2.5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had decreased from 42 to 26 in the three preceding weeks, rose to 46 last week, of which 23 occurred in Glasgow, 12 in Aberdeen, and 9 in Edinburgh. The deaths from whooping-cough, which had been 18, 25, and 27 in the

three previous weeks, further rose to 33 last week, and included 25 in Glasgow and 4 in Dundee. The fatal cases of scarlet fever, which had declined from 12 to 4 in the two preceding weeks, rose to 6 last week, of which 4 occurred in Glasgow. The deaths from diphtheria, which had been 5, 3, and 7 in the preceding three weeks, were 6 last week, and included 4 in Glasgow. The deaths from "fever," which had been 6 in each of the two previous weeks, were again 6 last week, and included 4 in Glasgow. The deaths from diarrhoea rose from 6 to 8 in the previous two weeks, and further increased to 17 last week, and included 9 in Glasgow and 4 in Greenock. One death from small-pox was recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 163 and 214 in the two preceding weeks, rose to 245 last week, and exceeded by 223 the number in the corresponding period of last year. The causes of 83, or more than 8 per cent., of the deaths in these towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31.9 per 1000 in each of the two preceding weeks, rose to 34.2 during the week ending Feb. 16th. During the past seven weeks of the current quarter the death-rate in the city has averaged 32.7 per 1000, against 20.5 in London and 23.7 in Edinburgh. The 229 deaths registered in Dublin during the week under notice showed an increase of 15 upon the number in the previous week, and included 17 which were referred to the principal zymotic diseases, against 16 and 19 in the two preceding weeks; of these, 8 resulted from small-pox, 5 from diarrhoea, 2 from "fever," 1 from diphtheria, 1 from whooping-cough, and not one either from measles or scarlet fever. These 17 deaths were equal to an annual rate of 2.5 per 1000, the zymotic death-rates during the same period being 1.7 in London and 2.5 in Edinburgh. The fatal cases of small-pox, which had been 7, 5, and 7 in the three preceding weeks, further rose to 8 last week. The 5 deaths referred to diarrhoea exceeded the number recorded in any recent week. The deaths from different forms of "fever," which had been 4 in each of the two preceding weeks, declined to 2 last week. The mortality from whooping-cough showed a marked decline from that recorded in recent weeks. The 229 deaths in Dublin last week included 27 of infants under one year of age and 79 of persons aged upwards of sixty years; the deaths of infants were below those recorded in any recent week, while those of elderly persons showed a marked further increase upon recent weekly numbers. Four inquest cases and 4 deaths from violence were registered; and 79, or more than a third, of the deaths occurred in public institutions. The causes of 16, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR MORRIS has left Bermuda on completion of a tour of service. Surgeon-Captain Kelly has arrived at Halifax. Surgeon-Captain Rawnsley has embarked for Malta on exchange, and Surgeon-Captain Tatham on troop duty. The following officers have arrived from India in the *Malabar*:—Surgeon-Lieutenant-Colonel Robinson, Surgeon-Major Le Moine, and Surgeon-Captains Elliott and Hassard. Surgeon-Major O'Sullivan has been transferred from Dublin to Belfast; Surgeon-Captain Browning, from Kilkenny to Limerick; and Surgeon-Captain McCormack, from Woolwich to Hounslow. Surgeon-Major Wilkinson has been posted to Aldershot on return from foreign service, and Surgeon-Major Hewett to the North-Eastern district.

ARMY MEDICAL STAFF.

The following appointments are gazetted:—Surgeon-Captains to be Surgeon-Majors: W. G. Macpherson, M.B.; R. J. S. Simpson, M.B.; E. V. A. Phipps; A. Baird, M.B.; F.R.C.S. Edin.; T. W. O'Hara Hamilton, M.B.; D. Sempie, M.D.; J. R. Stuart, M.B.; W. B. C. Deeble; R. P. Bond; G. T. H. Thomas, F.R.C.S. Edin.; G. M. H. Colman, M.B. Surgeons on probation to be Surgeon-Lieutenants: W. S. Harrison, M.B.; H. A. L. Howell; D. Lawson; E. B. Steel, M.B.; C. W. Profet, M.B.; F. Kiddle, M.B.; H. E. Staddon; J. H. Whitehead; J. A. Murison, M.B.; L. P. Tomlinson; S. J. C. P. Perry; and A. F. Heaton.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major F. A. Harris, A.M.S., has been appointed to the Medical Charge of the Station Hospital, Indore; Surgeon-Lieutenant William Carr Sprague having completed three years' full-pay service, to be Surgeon-Captain; Surgeon-Lieutenant H. W. H. O'Reilly, A.M.S., has been appointed to the Medical Charge of the Station Hospital at Calicut. The following appointments and transfers of medical officers have been ordered:—Surgeon-Lieutenant R. F. E. Austin, from the Bombay to the Sind district for general duty; Surgeon-Captain C. S. Sparkes, A.M.S., on arrival from England, to the Mhow district, for general duty; Surgeon-Captain B. D. Basu, I.M.S., to the Officiating Medical Charge of the 9th Bombay Infantry; and Surgeon-Captain T. W. Irvine, M.B., to the Officiating Medical Charge of the 7th Bombay Lancers.

NAVAL MEDICAL SERVICES.

The following appointments are notified:—Staff-Surgeons: M. O'Connell Macswiny to the *Barfleur*, and A. H. Miller to the *Mildura*. Surgeons: R. H. Nicholson, R. Hardie, and E. Cuffey to the *Scylla*; P. E. Maitland to Haslar Hospital; J. W. W. Stanton to the *Scylla*, and after to the *Pigeon*; G. T. Broatch to Yarmouth Hospital; J. W. O. Underhill to the *Barfleur*; and B. C. E. F. Gunn to the *Malabar*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain John Sutcliffe to be Surgeon-Major.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment): Surgeon-Major T. L. Gentles to be Surgeon-Lieutenant-Colonel. 4th (Perthshire) Volunteer Battalion, the Black Watch (Royal Highlanders): Surgeon-Lieutenant C. Brown, M.D., resigns his commission. 2nd London: Surgeon-Captain A. R. H. Oakley resigns his commission.

DEATH IN THE SERVICES.

Surgeon-Major Albert Richard Waghorn, M.D., Bengal Army (retired) at Redhill on the 6th inst. at the age of sixty-six. He served at the siege, assault, and capture of Delhi, 1857 (medal and clasp); and in the Bhootan Campaign, 1865 (medal and clasp).

ACCIDENT TO A NAVAL SURGEON.

We regret to learn that Surgeon Hugh St. David Griffiths met with an accident on Thursday, Feb. 14th, while travelling from Paddington in a corridor train. Through opening by mistake a door he was thrown on to the line, but fortunately was able to drag himself to a place of safety before the passage of an up train from Plymouth. The accident happened near Swindon, from which town assistance was promptly sent.

THE CANTONMENT BILL.

This Bill seems to have given rise to a great deal of discussion and consideration in India, if we may judge from the length of the speeches and the debate it caused in the Viceroy's Legislative Council, as reported in the public journals of that country. The Hon. Sir Griffith Evans made a long and weighty speech on the occasion, fully setting forth the history of the matter, which is a larger one than is commonly supposed, in that it affects the constitution of the Indian Government. A number of other speakers took part in the debate. The third section of the Cantonment Act Amendment Bill has been withdrawn, and very properly, for nothing could be said in favour of a most objectionable and unnecessary piece of legislation as far as the Government medical service of India is concerned. The second section stands, subject to such changes as may be made in it on the recommendation of a select committee to whom it was referred. It seems probable, however, that the matter will not end here should further experience prove that the prevalence of this class of diseases continues to increase and to cause even a greater amount of inefficiency than exists at the present time.

COMMISSIONED MEDICAL OFFICERS AND LOCAL GOVERNMENTS AND ADMINISTRATIONS.

The *Times of India* says: "With reference to a recent ruling of the Government of India, in which it was pointed out that commissioned medical officers whose services were placed at the disposal of local governments and administrations were sometimes thrown out of civil employment for short periods, the Government of India have decided to fix a definite maximum number of supernumerary officers which

each local government and administration (except Hyderabad assigned districts and Coorg, which it is considered should not be brought within the scheme) may retain in excess of those filling sanctioned appointments in the cadre of the Indian Medical Service. The following are the numbers that have been fixed: Madras, 4; Bombay, 4; Bengal, 4; North-West Provinces and Oudh, 3; Punjab, 3; Central Provinces, 1; Burmah, 2; and Assam, 1."

A GOORKHA ASYLUM.

A movement is on foot to establish near Simla an asylum for the maintenance and education of the orphan sons of Goorkha pensioners and for old soldiers in indigent circumstances. The proposal has received the approval of both the late and the present Viceroy, and many high officials in India. More than R.7000 have been collected in India, and the committee now ask for a similar sum from England. Donations should be sent to Messrs. H. S. King and Co., 45, Pall-mall, London.

INDIAN MEDICAL SERVICE DINNER IN WAZIRISTAN.

Members of the Indian medical service serving with the three brigades of the Waziristan field force made arrangements for a corps dinner at Ibandula, and accordingly on the 10th ult. twenty-eight medical officers, with a few of their combatant friends, dined together. Surgeon-Colonel Spencer, Principal Medical Officer of the field force, presided. Surgeon-Captain Gilbert managed the details with a successful result.

ALDERSHOT.

With reference to the rumours about the prevalence of enteric fever at this station, a correspondent, apparently acquainted with the facts, writing to the *Standard* says that there have been only four cases of that fever in the camp during the last six months in a military population of about 15 000. It seems, as he urges, unlikely that the water-supply or milk can have been the cause of the disease, otherwise cases would have occurred among the families and married people, or there would have been an outbreak of the disease on a larger scale; nor is it easy to explain how the water received its specific contamination.

MILK-SUPPLY IN INDIA.

The Government of India have deputed Veterinary-Major W. H. Kemp to inspect all dairies under military supervision, with the view of enabling the Government to arrive at a satisfactory conclusion on the question of the supply of pure milk to hospitals of British troops and troops generally in that country.

The *Broad Arrow* states: "It is notified in an Army circular just published that time on half-pay not exceeding one year shall be allowed to reckon as service in the case of an officer of the Staff Corps or of the Indian Medical Service placed on half-pay on account of ill-health contracted in the performance of military duty, and that such time shall also reckon as service for promotion. This period of one year's service on half-pay can only be reckoned by an officer on his restoration to full-pay, and he cannot be promoted whilst remaining on the half-pay list; but the period will reckon for pension, whether an officer retires direct from half-pay or after restoration to full-pay. Retrospective effect to the above concession will, where necessary, be given from Jan. 1st, 1887."

Advices from the West Indies station report an outbreak of yellow fever on board the ships of the British Training Squadron which were in quarantine at Bermuda. A number of cases have proved fatal, nine burials taking place within one week.

Brigade-Surgeon-Lieutenant-Colonel King, Superintendent of the Royal Botanical Gardens in Calcutta and Government Quinologist, has been granted an extension of service for two years in compliance with the recommendation of the Government of India.

Surgeon-Colonels Churchill and Maunsell, the Principal Medical Officers at Woolwich and Cork respectively, are held in readiness for service in India.

THE New Element will form the subject of a popular lecture at the Royal Victoria Hall on Tuesday, Feb. 26th, at 8.30 P.M. It is a sign of the times surely that scientific discovery should be expounded to the public at an admission fee of 1d.

Correspondence.

"Audi alteram partem."

"ANÆSTHESIA BY THE CHLOROFORM AND ETHER MIXTURE."

To the Editors of THE LANCET.

SIRS,—The article on this subject by Dr. Truman in THE LANCET of Feb. 16th is undoubtedly of great value, more especially as it opens up a field of research from which much useful information may be expected. With regard to this particular article, however, there are one or two points upon which I should like to be permitted to express some opinions. In the first place I think that attention should be drawn to the fact that the observations made by Dr. Truman apply to "a mixture of one volume of chloroform and two of ether," and cannot therefore be held to apply absolutely to what I believe is more usually referred to in England when we speak of "the" mixture; more often than not I fancy that this term is applied to the combination otherwise known as "the A.C.E.," containing one part by volume of alcohol to two of chloroform and three of ether. It is held by some that the addition of the alcohol is a most important factor in this particular combination, for it is maintained that not only does it tend to equalise the evaporation of the other constituents, but that it even retards the absorption of the chloroform. May I express the hope that at some future date, either through your columns or through the medium of the Society of Anaesthetists, Dr. Truman may give us his views upon these theories? The second point to which I would draw attention is that Dr. Truman speaks of the administration of his mixture by means of "Clover's inhaler"—i.e., an inhaler with a bag. Used in this way I quite agree with him that the proceeding would be most dangerous, for I take it to be one of the axioms of anaesthetics that closed inhalers (by which I understand any form of bag inhaler) are absolutely contra-indicated in the administration of any anaesthetic or combination of anaesthetics containing chloroform; not only is there the objection referred to by Dr. Truman of irregularity in evaporation, but there is also the still graver risk of the accumulation of a highly dangerous percentage of chloroform vapour in the bag. In the concluding sentence of his article Dr. Truman admits that by the open method the vapours would doubtless be more evenly distributed, and to my mind this very admission rather counteracts his previous deduction that when ether cannot be used unmixed chloroform should be employed. I quite agree with Dr. Truman in his preference for ether, but I hardly think that the observations recorded in his article justify the use of unmixed chloroform as the second string to one's bow. I think, however, that his observations are of the greatest value as emphasising the danger of administering chloroform in any shape or form by means of a closed inhaler.

I am, Sirs, yours faithfully,

J. FREDK. W. SILK.

Anæsthetist to Guy's and King's College Hospitals &c.
Weymouth-street, Portland-place, W., Feb. 18th, 1895.

To the Editors of THE LANCET.

SIRS,—I should like to make a few comments on the article on Anaesthesia by the Chloroform and Ether Mixture by Dr. Edgar Truman in the last issue of THE LANCET. His arguments against the use of this mixture are based on the rapidity of vaporisation of ether compared with chloroform, and hence, as shown by his analysis, that "the patient would be inhaling 100 volumes of ether to 0.953 of chloroform at the first, whilst..... at the last would be inhaling 100 volumes of ether to 75 of chloroform." Allow me to point out that from a practical point of view this is a desirable result, because it is the beginning of the administration which is the most dangerous time; therefore there is more safety at this period from the fact that the patient is chiefly breathing ether. When the patient is fully under, the increased proportion of chloroform in the vapour inhaled is of much less danger, and even at this period Dr. Truman admits that there is an excess of ether over the chloroform. In conclusion, I may state that the increased

safety of the mixture compared with the use of chloroform alone is obvious to anyone who has had experience of both.

I am, Sirs, yours faithfully,

C. F. MARSHALL,
Late Anaesthetist to the Hospital for Sick Children,
Great Ormond-street.

Charing-cross-road, W.C., Feb. 16th, 1895.

"THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—Dr. Lovell Drage has resorted to a common dialectic device and gone off at a tangent to discuss questions which were not raised in the letters written by Sir John Williams and myself—viz., the examination and registration of midwives. His views on these topics are well known, and I must beg him to excuse me if I do not follow him into so useless a controversy. So far as I know, the General Medical Council has expressed no opinion upon them, and there is no reason to suppose that it has formed one unfavourable to either. What the Council has done is to inform the Obstetrical Society that it has arrived at the conclusion, apparently formed after hearing one side of the question only, that its diploma is liable to the objection of being a colourable imitation of a "licence to practise medicine, surgery, and midwifery." As soon as possible after the receipt of this resolution the society resolved not to issue any more diplomas until a form was decided upon satisfactory to the Council. The society was not asked to discontinue its examinations, and I do not know what more it could have done; but the society may, I think, reasonably complain of the needlessly offensive and irritating terms in which the resolution was couched. I have been taken to task for calling the resolution "insulting"; but surely it is nothing less than insulting to a body of honourable men, banded together to promote the welfare and progress of an important department of medicine, to associate with its work such a formula as "infamous in a professional respect," hitherto restricted in its application to the most degraded and ignoble members of the profession? I have been informed by a member of the General Medical Council that this resolution was passed because the Council believed that repeated representations had been made to the society which had received no answer. No such repeated representations ever reached the society, and this plainly indicates very slipshod and ineffective business arrangements on the part of the Council. In any analogous case in private life should it be shown that action was taken on unfounded premises explanation would certainly be made. I do not see why the Council as a body should not be expected to respect the courtesies and amenities of life, which its members would certainly attend to in their private and individual capacities. Perhaps you could find space to print this famous diploma, of which I enclose you a copy, so that your more impartial readers may judge for themselves whether it is or is not a colourable imitation of a "licence to practise medicine, surgery, and midwifery."

I am, Sirs, yours truly,

W. S. PLAYFAIR.

George-street, Hanover-square, Feb. 16th, 1895.

[COPY]

OBSTETRICAL SOCIETY OF LONDON.

We hereby certify that
has passed to our satisfaction the examination instituted by the
Obstetrical Society of London, and is, in our opinion, a skilled midwife,
competent to attend natural labour.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."

To the Editors of THE LANCET.

SIRS,—In replying to that part of Dr. Pavy's last letter which alone concerns me I will be as brief as possible; but to make the position clear I must begin by a somewhat long extract. After saying that it is the actual presence and not the quantity of sugar in normal urine that he has contended for, he proceeds to say: "Sir George Johnson has based arguments upon the quantity he says I have asserted to be present. I have not, however, committed myself to anything absolute upon this point. My statement contains

the provisional 'if' to meet the doubt that existed in my mind. It runs thus: 'If the cupric oxide reduction found to occur [after treatment with the neutral and basic lead acetate] be read off as produced entirely by sugar, the amount of this principle ordinarily existing in healthy urine may be said to stand at about 0.5 or a little over per 1000. As long as Sir George Johnson only quoted me imperfectly I did not consider it necessary to take any notice, but Dr. Halliburton at the end of his letter falls into the same imperfect representation.' It is remarkable that not only I and Dr. Halliburton, but Dr. Noel Paton¹ also, failed to discover how much was concealed beneath Dr. Pavy's "provisional 'if,'" and thus, not seeing what was in the author's mind, we are charged with having quoted him imperfectly. Let me remark in passing that Dr. Pavy, referring to Dr. Halliburton's admission that a small amount of sugar is obtainable from normal urine, omits to quote the following sentence: "Whether this is artificially produced by the method of analysis as suggested by Sir George Johnson is a subject that demands renewed research." I will not follow Dr. Pavy's example by suggesting that this omission is an "offence to literary probity."²

In a letter of mine which was published in THE LANCET of July 21st, 1894, occurs the following query: "Does Dr. Pavy still maintain, as he did in his paper in vol. lxiii. of the Transactions of the Royal Medical and Chirurgical Society, that while one-fourth of the reducing action of normal urine upon cupric oxide is accounted for by uric acid, the remainder of the reduction, which would amount to at least half a grain of glucose per ounce is 'due to the small amount of sugar naturally present in urine?' and, further, 'it is doubtful if there is any other body worthy of consideration to produce any reducing effect.'" To this question Dr. Pavy made no reply, his reason, perhaps, being that as "Sir George Johnson only" asked the question he "did not consider it necessary to take any notice." It is evident that when Dr. Pavy's paper was published in 1880 he knew nothing of the existence and the reducing power of urinary kreatinine. At that time this want of knowledge was excusable, but since then it has been proved that the removal of kreatinine from normal urine leaves no reducing agent in the filtrate; and yet further that the amount of reduction effected by normal urine having been accurately determined a solution of kreatinine of the same indicated strength causes an equal amount of reduction, whether determined by the cupric oxide or by the picric acid method. It is inconceivable that so accomplished a physiologist and chemist as Dr. Pavy can be ignorant of these now notorious facts, and it is probable that beneath the "provisional 'if'" there is concealed more than has hitherto been revealed to the ordinary reader. I venture to suggest that in the sentence which Dr. Pavy has quoted from his book if the word "kreatinine" were substituted for "sugar" the only inaccuracy would be in the estimated amount of reduction. Numerous careful observations have shown that the average amount of reduction in normal urine excluding uric acid is 0.8 grain per fluid ounce calculated as glucose, indicating in round numbers about a grain of kreatinine to the fluid ounce of urine, which is equivalent to 0.23 per cent. by weight of that substance.

I am, Sirs, yours faithfully,

Savile-row, W., Feb. 18th, 1895.

GEORGE JOHNSON.

To the Editors of THE LANCET.

SIRS,—I am sorry that my letter on this subject should have raised so much feeling on Dr. Pavy's part. The only point I feel bound to answer is Dr. Pavy's statement that I have misquoted him. At the conclusion of his account of the experiments I referred to Dr. Pavy writes: "The circumstances observed stand, it is to be remarked, in accord with the statement of Pasteur that acidity opposes, while alkalinity favours, the occurrence of fermentation." From this I somewhat naturally concluded that Dr. Pavy had been dealing with alkaline solutions. But even if the solutions were absolutely neutral it is difficult to understand how the neutralisation of strongly acid substances can be accomplished by sodium carbonate without the evolution of carbonic anhydride. If for no other reason than this I still feel bound to adhere to my previously expressed opinion that the use of sodium carbonate for neutralisation is a source of error in the fermentation test.

¹ Edinburgh Medical Journal, December, 1894.

² See Dr. Pavy's letter in THE LANCET of Feb. 9th, 1895.

Evolution of carbonic anhydride would occur even more rapidly if the solutions are neutral than if they are alkaline; for if the solutions are strongly alkaline there is a liability of sodium bicarbonate being formed, and thus little or no free gas makes its appearance.

Since the foregoing paragraphs were written I have learned, in conversation with Dr. Pavy, that he neutralised with sodium carbonate several hours, and in some cases days, before the application of the fermentation test. This, one must freely admit, alters the case, for one cannot but suppose that all decomposition in which sodium carbonate took place would be over by that time. It would perhaps have been well if Dr. Pavy had stated this originally, for observers who tried to repeat his experiments would otherwise have fallen into the source of error of which the first part of this letter speaks. For those who work rapidly, I think Dr. Pavy will himself admit that it would be wiser for them to adopt some other alkaline material for the purpose of neutralisation. The object of such a correspondence as this is, I take it, to get to the truth of the matter, and would it not assist us in so doing if Dr. Pavy would amplify his position in other directions also? For instance, in speaking of the detection of alcohol Dr. Pavy alludes only to the chromic acid test. Now this test is given by several volatile organic substances. It would, therefore, add to the value of this discussion if Dr. Pavy would state whether other tests were applied for the identification of alcohol. Then, too, there is the question of kreatinine. If Dr. Pavy would state definitely once and for all his opinion on this matter we should be nearer a solution of the difficulty between Sir George Johnson and himself.

I am, Sirs, yours faithfully,

W. D. HALLIBURTON.

Ridgmount-gardens, W.C., Feb. 18th, 1895.

"SCHOOL BOARDS AND MEDICAL CERTIFICATES."

To the Editors of THE LANCET.

SIRS,—The question of signing School Board certificates has been constantly before us in this district. I always refuse to sign them or allow my house surgeon to do so, telling the applicants that if summoned I will attend as a witness on their behalf. This would result in the cases being dismissed with costs against the School Boards, and consequently they never adopt this procedure. Recently one of them wrote to my committee requesting that it would direct these certificates to be signed. I explained that they were not wanted by the children or their parents, but by the School Boards, and as I was not a servant of the School Boards they were not entitled to my gratuitous services. My committee sent a reply to the effect that the question of certificates for School Boards had nothing to do with it, its duty being only to administer the hospital for the benefit of the poor. Surely School Boards ought to have paid medical officers to whom they could refer all such cases.

I am, Sirs, yours faithfully,

ROBERT W. DOYNE.

Surgeon, Oxford Eye Hospital.

Oxford, Feb. 18th, 1895.

THE ABUSE OF MEDICAL CHARITIES.

To the Editors of THE LANCET.

SIRS,—The following case is a good example of the above. Three weeks since a patient upon whom I had operated for ovarian disease eight years since came to me with a like tumour of the other ovary calling for immediate removal. The fee was arranged, after the now usual wish expressed (save probably in some special instances) to have this moderated to any possible extent, but the only reason the husband could offer was that his money was locked up in his business. As it was inconvenient that the operation should be done at her own house, which was also the place of business, it was arranged that it should take place at a nursing home where other of my cases have been, and the cost of such was not objected to. A few days later I received a note from the husband, enclosing a letter of admission to the paying wards of the Hospital for Women, Scho-square, and asking me to sign that portion of the form stating that the patient was from my "personal knowledge" a fit and proper person to be admitted to these wards at the payment of one guinea per week. This, I pointed out to the husband, I could not do. I wrote to the

secretary of the hospital stating that I had refused to do so, and adding that I was satisfied they would find on inquiry that the patient was not a proper person for hospital relief. I enclosed a printed memorandum heading showing that the husband was a partner in the firm, and giving the address. I would here add that on the earlier occasion of my operating, when my fees and those of a medical man whose immediate patient she then was were cheerfully paid, the husband was only a servant of the then existing firm. A few days later the secretary wrote me (Feb. 7th) that he had "laid my letter in reference to Mr. —'s case before the committee of management, and am instructed by them to inform you that after due inquiry they have satisfied themselves that the case is a proper one for admission to the hospital." Comment is needless.

I am, Sirs, yours faithfully,

Phillimore-gardens, W., Feb. 19th, 1895. WILLIAM TRAVERS.

"FEVER AND SMALL-POX HOSPITALS."

To the Editors of THE LANCET.

SIRS,—In connexion with the leading article with this title in THE LANCET of last week on a memorandum on isolation hospitals by the medical officer of the Local Government Board, in which you express your disagreement with those who seek to limit the power of diffusion of small-pox, I should like to say a few words.

In the paragraph of my report, which you quote, the extreme limit of diffusibility is put at 1000 feet. My reasons for this opinion were based upon one year's experience of the complete immunity of a considerable population residing in public institutions at about this distance from a small-pox hospital. The number of patients who passed through the small-pox hospital during the year was 1563, all of whom were admittedly in an undoubtedly infectious condition. There were good reasons for supposing that the inmates of the institutions referred to were on about the same footing as regards protection from small-pox as the general public. Why, then, should the question of vaccination and convalescence be used as arguments to invalidate the conclusion at which I arrived? The argument as to convalescence appears to me to be simply a begging of the question. Whatever sense is attached to this term by the officers of the Local Government Board, the fact remains that the patients were all infectious when admitted, and were discharged as soon as they were free from infection. The experience to which I drew attention in my report may or may not be solitary, but it is not capable of explanation, in my opinion, on the grounds given in your article; and it is opposed to the view of those who hold to any higher degree of diffusion than the 1000 feet limit.

I am, Sirs, yours obediently,

C. E. MATTHEWS.

Fountain Hospital, Tooting, Feb. 20th, 1895.

"AN APPEAL."

To the Editors of THE LANCET.

SIRS,—I was truly grieved to learn from Mr. Upton's letter in THE LANCET of Feb. 16th that the widow of Professor G. J. Guthrie is practically penniless. I do not know why she was left unprotected for; but I do know that every member of the profession, whether he is aware of it or not, is indebted to Guthrie for the work which he embodied in his "Commentaries on the Surgery of the Peninsular War"—especially on the subject of the treatment of hæmorrhage. Guthrie's work was almost always heavy and anxious; yet in spite of all difficulties, and often of danger, he went on collecting, examining, and describing the specimens which were to prove his views. "At Toulouse a large shot struck an officer and nearly tore off the right thigh. I saw him shortly afterwards every indication of approaching dissolution. The house being close to one of the French redoubts the fire of round shot and musketry was so severe as to induce me to remain until the battery should be taken by the troops then advancing upon our flank. To occupy my time usefully I returned to the officer and found he had just expired. Desirous of seeing by what means the hæmorrhage had been arrested I cut down upon the artery, took it carefully out, and found," &c. Thus Guthrie obtained the facts which definitely settled the principles of treatment in cases of hæmorrhage. Surely, Sirs, we as a profession will not allow the widow of such a worker to die of want. I trust that at least treble the amount asked for by Mr. Upton will

be promptly promised and in the form of annual subscriptions. A guinea or two a year from a few of us during the rest of Mrs. Gathrie's life is all that is wanted to enable her to end her days free from the terrible strain of pecuniary anxiety.

I am, Sirs, faithfully yours,
Harley-street, W., Feb. 19th, 1895. STANLEY BOYD.

"MEDICAL WITNESS AND JUDGE."

To the Editors of THE LANCET.

SIRS,—In an annotation under the above heading in THE LANCET of Feb. 16th the expression "there was no evidence that penetration had occurred" was a "correct phrase" and "logical inference" from the facts of the case—i.e., penetration may or may not have occurred, but if it had there was no proof or evidence of it. A purulent discharge is no proof of penetration, nor is semen, pus, and epithelial scales on the shirt of a prisoner. The prisoner was examined a few days after the alleged assault by the gaol surgeon and found to have no discharge. I was a scientific witness and had to deal with other conditions observed by myself, and not "presumptive evidence," that being a matter for the judge and jury. I based my opinion upon my examination and not upon the evidence of the prosecutrix.

I am, Sirs, yours faithfully,
Southsea, Feb. 16th, 1895. LYSANDER MAYBURY.

"THE CONSUMPTION SCARE."

To the Editors of THE LANCET.

SIRS,—Referring to the leading article under the above heading in THE LANCET of the 22d inst. I venture to ask your indulgence in order to point out one or two matters in connexion with this subject which are not commonly recognised, and which should rouse the public care and interest to preventive action.

We all have brought before us day by day the serious consequence of the marriage of phthisical persons; it may be the disease is not hereditary, but the predisposition is acknowledged to be hereditary, and I have seen whole families swept away miserably. I have seen others live, perhaps, more miserably; for instance, where both parents are phthisical and unable to gain a decent livelihood. I have seen a family growing up afflicted in all sorts of ways, with brain disease, mesenteric disease, and still increasing in numbers. I remember cases where whole families of eight or nine have died, chiefly from meningitis, and I feel sure that many of the parents would not marry if they knew clearly their responsibility and there were homes to which invalids could go. It is known that cows which are tuberculous exist in sheds, and there is no law by which they can be seized, although we are told by the best authorities that the milk of such cows is a chief cause of tuberculous disease in children. We can forbid the sale of the milk if we can catch people selling it, but we cannot touch the cow; then clearly power is wanted to destroy the cow and compensate the owner. Authorities tell us that 10 per cent. of cattle slaughtered are tuberculous, and we know that diseased carcasses of all sorts are sent off to towns, and there seems no protection against this if the viscera and ribs are kept back and sold in the country, where the inspector of nuisances is not often capable of detecting disease, nor is he likely to supervise properly 200 or 300 slaughter-houses scattered through his district—probably the police might be trained to do this. Rows of old, dark, dilapidated, damp, dirty houses with little air space continue to exist in spite of the attempts to abolish them when we know that sunlight and pure air, with strict cleanliness of floors, walls, and furniture, are necessary for protecting children from the attacks of this destructive disease.

Dr. Cornet points out that beds, especially at lodging-houses and hotels, are probably a source of danger, and this opinion has long been held in Malaga and other resorts of the phthisical, yet we all see day by day lodging-houses where lodgers follow one another for 3d. per night's accommodation, but the sanitary authority has no power to order the disinfection of the beds from time to time, while the practical remedy seems to be that the authorities should have some power to order spring mattresses to be covered with blankets and straw pillows, and the blankets to be boiled at defined intervals. As a rule, there is no proper steam disinfecting apparatus for beds in small places, though many decent people would like

their beds purified, after disease particularly. I know of no homes, excepting the cottage homes which Dr. Trudeau has established near the Adirondack Mountains, where a young man or young woman warned of tuberculous disease or tendency can go, and not one where they may live quietly and partly gain their independence by a pleasant easy occupation such as fruit, flower, rose, or vegetable growing under glass, or where, as in the highlands of the Cape, Australia, Peru, or California, they may in the bright, dry atmosphere of the mountain or near the sea hope to recover their health by occupation in the pure air. Monasteries and abbeys have been, and are, established for more or less useful purposes perhaps, but I am aware of no home, no wealth, no intelligent energy devoted to so noble an object as restoring health to the sick phthisical and partial independence to those in delicate health inherited from phthisical parents who ought not to marry and desire to engage in some useful healthy occupation. It seems as though we preferred to pay for crippled lives of children and slow deaths in preference to taking any trouble to prevent such things, or otherwise the subject is not understood by the public, and some scare seems wanted to rouse the public conscience to such dangers as exist.

I am, Sirs, your obedient servant.

M.O.H.

"THE REMUNERATION OF THE RESIDENT OFFICERS IN ST. BARTHOLOMEW'S HOSPITAL."

To the Editors of THE LANCET.

SIRS,—With regard to the letter on this subject which appeared in THE LANCET of Feb. 9th, there is, I think, no doubt that payment of a fee or having to board oneself during a resident appointment may be to a few a positive hardship, coming as it does at the end of a long and expensive curriculum, when many feel the necessity of at least earning enough to help themselves; but at the same time "Fair Pay" is hardly in keeping with his title when he calls the system a sweating one and states that the resident gives time and health up for no return. The very fact of having held an appointment at a hospital belonging to a medical school is invaluable in after life. It brings a man into constant personal contact with some of the leading members of the profession; it gives him confidence in himself; it is the best stepping-stone to other appointments; and, in short, is the very best start a man can make after getting qualified. Surely, then, these are some returns for the time given, returns no doubt largely depending on the personal factor in the case, but in most cases incomparable to the small amount that may actually at the time be lost out of pocket. St. Bartholomew's is not the only hospital where a fee is charged. At Middlesex the fee is £10 10s. for a six months' appointment, but there the resident is boarded and lodged free of further charge, and I believe there are also other hospitals where a small fee is charged.

I am, Sirs, yours faithfully,

Feb. 18th, 1895.

LATE HOUSE PHYSICIAN.

To the Editors of THE LANCET.

SIRS,—It is because I am an old resident at other hospitals as well as at St. Bartholomew's, and because I know the difficulty in obtaining reforms from hospital committees, especially when it is a question of finance, that I broached the above subject in your columns. I admit with your correspondent, "An Old House Surgeon of St. Bartholomew's," that the experience gained as a resident there is invaluable, and that one has a "general good time"; but I do not think men join hospitals as junior officers for the latter purpose, nor should I think it worth while to pay £50 for it. The main point is that other hospitals not so well off can support their residents, then why not St. Bartholomew's. Personally I blush for my *alma mater* when I compare it with other institutions in this matter, and I feel sure that the present system must prevent some of its students who cannot afford a "good time" from applying for the various posts which would otherwise be open to them. I have not actually come across such a case, but I have not the least doubt that they exist. Your correspondent knows as well as I do that while men are resident in the hospital they have not the opportunity of broaching such a subject as this, nor would they be listened to if they did. Except as an old student of the hospital it does not concern me now; but it did very much once, and I venture to think that should this correspondence

help ever so little in hastening the better payment of these officers, which I am confident will be accomplished ere long, it will not have been in vain.

I am, Sirs, yours faithfully,

London, Feb. 16th, 1895.

FAIR PAY.

To the Editors of THE LANCET.

SIRS,—Many past and present students of St. Bartholomew's will agree with "Fair Pay" in his strictures upon the governing body of the richest hospital in London for making it necessary that a man should spend £50 (and this a minimum) if he obtains a house physician's or house surgeon's appointment. In my own case, after I qualified I was offered a house appointment at St. Bartholomew's at a definite date, and was unable to accept it owing to the expense involved. At the time I left the hospital—not more than four years ago—I knew of two or three men in a similar position to myself in this respect.

In his reply to "Fair Pay's" letter "An Old House Surgeon of St. Bartholomew's" asserts that this is a question of no concern to anyone unconnected with the hospital. His own letter shows why it is of interest to the profession in general, for it is important for the profession to see that house surgeons are taught by this improper system that their relations with other medical men are to be regulated by no other consideration than the "law of supply and demand" in its money sense, and that "An Old House Surgeon of St. Bartholomew's" has learnt his lesson so well that he allows himself to rejoice at having had "a general good time" at the expense of his poorer contemporaries.

I am, Sirs, yours faithfully,

Feb. 18th, 1895.

R.M.O.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary.

THE annual meeting was held the other week, and the report shows that this, the oldest medical charity of Manchester, is still growing and extending. During the year 1356 patients have been treated within its walls. There have been 33 889 out-patients, 970 have been treated at their own homes, 2633 have been received at the Monsall Fever Hospital, and 1610 have been sent to the Convalescent Hospital at Cheadle. The expenditure has been as follows: Royal Infirmary, £17,999; Convalescent Hospital, £5518; and the Monsall Fever Hospital, £13 865. The Infirmary, however, is not large enough for the demands made upon it, and there is much perplexity as to the best method of increasing the number of beds, of providing administrative requirements, and the means and appliances necessary for the complete equipment of a modern hospital. This difficulty is increased by a resolution of the trustees, passed in 1892, which forbade the covering of more land than is occupied by the present building. Strong objection has been expressed from time to time in the City Council to any further encroachment on the surrounding space, and on this point the Council may be taken as a reflex of public feeling. Various schemes for enlargement have been suggested, but two only seem feasible. The first and best would extend the front, and so form two additional wings, which would add 100 beds and give space for the other requirements; but it is blocked by the resolution of 1892. By the second another storey would be put on the present building. The adoption of either plan would be a mistake—indeed, a misfortune. Though the sanitary condition of the Infirmary is good and the patients do well, the perpetuation of antiquated structural defects, such as long gloomy corridors, which add greatly to the difficulties of ventilation, would be deplorable. Far better would it be to pull it down altogether. A new hospital might be built on the present site giving the required accommodation, and if necessary the nurses could be domiciled in the immediate neighbourhood.

Price of Gas and of the Electric Light.

A long discussion took place at the last meeting of the City Council as to the price of gas. The gas committee recommended the Council to abolish the charge for the hire of gas-meters and to reduce the price of gas used within the city for other than lighting purposes from 2s. 6d. to 2s. per 1000 feet. It was further recommended that "the price of

electric current be reduced from 8d. per unit to 6d. per unit," and to long-hour consumers that the present charge of 2d. per unit, with fixed charge equal to 4s. per quarter per lamp, be continued. In the end it was resolved that meter rent should be abolished and that the price of gas should be reduced to 2s. 3d. for all purposes. This will to some extent encourage the use of gas for domestic purposes and for gas-engines in place of small steam-engines, with a proportional clearing of the air from smoke. There remains the drawback, however, of a great excess of sulphur in the Manchester gas. It is a serious evil, towards the removal of which more ought to be done than is at present apparent. The reduction of 25 per cent. in the price of the electric light will tend to popularise it still more, and it is already becoming a serious rival to gas.

Manchester Hospital Work Society.

The above society held its sixth annual meeting recently, and the report shows how usefully it supplements in some directions the work of medical charity. It is mainly concerned in providing and distributing to the various hospitals articles of clothing corresponding as far as possible with the number of beds in the hospitals supplied. "The total number of beds in the sixteen hospitals is 1657, and the number of garments provided 1643. The committee continue to receive from the authorities of the different hospitals reports which abundantly testify to the beneficial effects resulting from the use of garments supplied for ward purposes by the society." It may be mentioned that the honorary treasurer and secretary are the wives of medical men.

Provident Dispensaries.

The working of these institutions as at present conducted may be illustrated by the report presented at the annual meeting of a branch dispensary in Salford. After expressing pleasure at there being a favourable balance the report proceeds as follows: "We also again beg to remind the members (and the public generally) that this dispensary is in no sense a charity, as each person pays for what they actually receive in time of sickness." The grammar may be passed over. It goes on to urge the members to request their friends and neighbours to join, for by so doing "they incur no heavy doctors' bills, and have no need to apply for free medical aid. There is no wage limit, so that application for membership is open to all." At the beginning of the year this dispensary, which is no charity, had 3074 paying and 3724 gross members. What gross members are does not appear, but the numbers had increased to 3214 paying and 4343 gross members. "During the year there have been 7765 consultations with the medical officers, in addition to many visits made at members' own houses." The gross profit for the year was £75 19s. 5d., of which £12 went to the Council of the Provident Dispensaries Association, "and the balance, £63 19s. 5d., was divided among the medical officers in proportion to the number of members attached to each." The dispensary has a reserve fund of £322 8s. 10d. It appears, therefore, that for each of the 7765 consultations a member of the medical staff was rewarded with something less than twopence, and the many visits to the members' homes were given in. If the value of the consultation is also less than twopence to the suffering member, it must also be remembered that he is in no sense a charity patient, "as each person pays for what they actually receive in time of sickness." Perhaps, however, the medical practitioner looks on it differently, and appraises the value of his services somewhat higher. It would seem a pitiful business. Anyone may join the dispensary, whatever his means, and may have a consultation for less than twopence.

The Clinical Hospital for Women and Children.

The annual meeting was held yesterday, and the report was an echo of those from most of the other charities. The out-patient department has been brought to the front of Cheetham Hill-road, with the result of very largely increasing the number of out-patients—viz., from 9517 in 1893 to 10,573 in 1894. The number of in-patients had been: women, 180; children, 725; somewhat fewer than in 1893. The Chairman said more money was wanted. They had spent £746 more than the income. The annual expenditure was £3000, and of this £1000 came from the Hospital Sunday and Saturday Funds, £1000 from investments, and for the other £1000 they had to depend on subscriptions and donations. A deficiency of £746 brings the amount derived from the last source down to £254, a somewhat sorry sum. In truth, the support of the various charities devolves on the few, who

give generously, and but little on the many, who give next to nothing. If those of the 700,000 inhabitants of Manchester and Salford who could without inconvenience give a small sum were to do so a different state of things would exist; but, it is to be feared, for a time only. There would still be the competition among the hospitals and the increasing willingness of the people—not of the poorest class only—to receive medical attendance without payment, so that the demands on the resources of the hospitals would increase apparently *pari passu* with their means.

Feb. 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Contract Bread.

AN action by a baker was recently brought in the County Court here against the King's Norton rural sanitary authority for £25 for breach of contract. There was a counter action for £55s. for breach of contract by the plaintiff. It seems that a contract was entered into for the plaintiff to supply the Infectious Hospital with bread made with best seconds flour at 4d. per 4lb. loaf. The evidence of the hospital steward showed that the bread was imperfectly made and unfit for patients, some of whom were paying patients; it was doughy, heavy, and not sweet. A medical man who happened to be a patient for six weeks gave corroborative testimony that the bread was dark in colour, coarse, and badly baked, but that the climax was reached when on cutting his bread one day he found the body of a cockroach inside. A verdict was given for the defendants on the claim, and for the plaintiff on the counter claim. Bread according to sample should evidently be looked after by the officers of such institutions.

The Dangers of Home-made Medicine.

A singular action was brought lately by a man against a firm of druggists to recover £50 damages alleged to have been sustained by the negligence of the defendants' servants in supplying to the plaintiff for the use of his wife a quantity of quinine greater than that demanded. The evidence went to show that at the defendants' shop was a notice "prescriptions accurately dispensed." The plaintiff's wife had neuralgia and he went to purchase five grains of quinine, for which he paid to a boy in charge of the shop 2½d. Having mixed the quantity given with port wine he gave some to his wife, who became very ill afterwards and remained so for some weeks. On returning to make inquiries it was found that five drachms had been given instead of five grains, the boy in charge admitting that he did not know the scales or the weights or the drugs. It was pleaded, in defence, that in law the defendants had no duty to the person to whom this drug was administered, and that there was contributory negligence on the part of the husband who had made the mixture. The judge summed up against the plaintiff both upon the facts and the law; he thought that there was contributory negligence on the part of the man, and he also held that there was no duty to the woman.

District Nursing.

The annual meeting of the District Nursing Society was held on the 14th inst. The report stated that the visits of the nurses had been 6000 in excess of the previous year. The expenditure had exceeded the income by £100. The usual votes of thanks were passed.

The National Society for the Prevention of Cruelty to Children.

The branch of this society located in this city is doing useful and valuable work in the direction of its aims. The annual meeting held on the 18th inst. showed that the number of cases dealt with was 425—namely, for neglect, 310; ill-treatment, 69; causing to beg, 17; assault, 12; exposure, 8; immorality, 3; other wrongs, 2. This is a lamentable roll in a civilised community, and worthy of the attention of philanthropists and benevolent people. It was stated that the National Society was £4000 in debt. Last year the branch sent £242 to the parent society, this year £101. The objects of the society were forcibly pointed out by different speakers and credit given to the officers for the careful manner in which the prosecutions had been conducted.

Feb. 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The University Court of St. Andrews.

A SPECIAL MEETING of the University Court of St. Andrews was held at the end of last week. The object for which the meeting was called was to reconsider the decision of a previous meeting respecting the Bill proposed to be introduced into Parliament having for its object to annul the affiliation of University College, Dundee, to the University of St. Andrews; and also to reconsider the decision regarding the foundation of two medical chairs out of the Berry Bequest, as has already been intimated in THE LANCET. Professor Purdie moved that the motion in favour of the Bill to annul the affiliation be rescinded, and this motion was seconded by Lord Provost Low. The amendment moved by Mr. Scott, and seconded by Dr. Balfour, was to the effect that it was undesirable to reopen the question. The motion was carried by 9 votes to 8. There was also read to the meeting an extract minute of the Senatus Academicus showing that the Senatus had by 11 votes to 4 passed a resolution disapproving of the proposed establishment of two additional medical chairs out of the Berry Fund. There was also read a communication from the Students' Representative Council stating that at a mass meeting of the students a resolution deprecating the decision of the court regarding the foundation of medical chairs had been carried by 93 votes to 3. Professor Knight moved: "That the University Court, having reconsidered the decision, do come to at its meeting on Jan. 26th, rescind the same, and refers the subject of the proposed medical chairs back to its business and finance committee, with instructions to bring up a report on the whole distribution of the Berry Fund at the earliest possible opportunity." Dr. Balfour moved and Dr. Dow seconded: "That the court adheres to the resolution as to the foundation of two additional medical chairs." This amendment was carried by 8 votes to 7.

Health of Edinburgh.

Small-pox still asserts itself in Edinburgh. Last week the fresh cases intimated numbered 12. The epidemic of measles also continues, 539 cases having been intimated last week, while there were 10 deaths. Thirty-seven fresh cases of scarlet fever were also intimated.

Economy at the Edinburgh Royal Infirmary.

At the meeting of managers of the Royal Infirmary on Monday it was intimated that there had been a decrease in expenditure for the quarter ending Dec. 31st of £876. As this does not seem to imply any diminished efficiency the result is most satisfactory.

Royal Edinburgh Hospital for Sick Children.

The annual report of this hospital shows that during the year 665 cases have been treated in the wards, while at the dispensary 8076 cases have been attended to. The income was rather more than £700 in excess of the expenditure. The amount received for the building fund was £6391, and it was intimated that the new hospital was expected to be ready before next winter. Money is urgently needed for carrying on to a satisfactory completion the erection and maintenance of this useful institution.

The Weather in Edinburgh.

The continued severe frost has led to much discomfort in Edinburgh, many houses having their water-supply entirely cut off by frozen water-pipes. At the end of last week, when there was a short thaw, much damage was done by flooding from burst pipes. People in many streets are being supplied with water in buckets directly from the mains. The continued frost has also told heavily upon the poor and the working classes, but measures are being taken to provide food and fire for the poorest.

Public Health of Glasgow.

During the past week the city death-rate has been exceptionally high, being at the rate of 43 per 1000 of the population per annum, a rate which has not been equalled for at least twenty years, though before that date such a mortality was not uncommon. In the previous week the rate was 32, while in the three preceding years during the periods corresponding to last week the rates were 20, 22, and 22. This alarming mortality does not seem to be due to any epidemic, though influenza has been very prevalent for at least a

fortnight; it is ascribed to the present extremely cold weather, many of the very young and very old, and those suffering from chronic chest ailments, being cut off. Small-pox has spread slightly, as was expected; three cases have been discovered during the week, and the number now in hospital is forty.

Association for Relief of Incurables, Glasgow.

From the report of this association it appears that its "Home" started last year with 94 patients, 16 were admitted during the year, and there had been 8 deaths and 6 removals, leaving 96 at the beginning of the present year. The number of those receiving out-door relief is 187. In the twenty years of its existence this association has given help to 850 out-door patients and 434 in-door, making a total of 1284. The financial year closed with a credit balance of £7 3s. 1d.

Feb. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Regulations as to Revaccination.

AN Order in Council, published in the *Dublin Gazette*, defines the regulations that shall apply to revaccination by medical officers in dispensary districts in Ireland. The revaccination of persons applying for the purpose shall be limited by the following conditions: (1) that the person has attained the age of ten years, or if there be an immediate danger of small-pox the age of seven years; (2) that the person has not before been successfully revaccinated; (3) that there are no circumstances present which would render the operation undesirable; and (4) that the medical officer can afford lymph for the purpose without interfering with the performance of primary vaccination in his district.

Royal University of Ireland.

At a meeting of the Senate held last week the Royal warrant appointing Mr. M. F. Cox, L.R.C.S., a member of the Senate was received. The following medical gentlemen were appointed Fellows of the University:—George Sigerson, M.D., R. O. Cunningham, M.D., A. E. Birmingham, M.D., John J. Charles, M.D., Denis J. Coffey, M.B., Patrick J. Hayes, M.D., John J. Lynham, M.D., Joseph P. Pye, M.D., Wm. Thornley Stoker, M.D., and Johnson Symington, M.D. The following examiners were elected for the ensuing year:—In Medicine: Joseph F. O'Carroll, M.D. In Midwifery: John W. Byers, M.D., and Alfred J. Smith, M.B. In Medical Jurisprudence and Hygiene: Chas. Y. Pearson, M.D., and Antony Roche, M.R.C.P. In Materia Medica: F. J. Quinlan, M.D., and Wm. Whittle, M.D. In Ophthalmology: J. Walton Browne, M.D., and Louis Werner, M.B. In Pathology: James L. Smith, M.D., and Edmond J. McWeeney, M.D. In Sanitary Science: Sir Charles A. Cameron, F.R.C.S.I.

Sir Patrick Dun's Hospital.

A bazaar and *fête* will be held next May at Ball's Bridge in aid of the funds of this institution, which, in consequence of the land agitation, has had its endowment revenue permanently decreased by £1000 a year. This hospital was founded in 1800, and was partially endowed by Sir Patrick Dun. For many years it only admitted medical cases, and during the famine years of 1826-8 and 1846-8 upwards of 10,000 cases of fever were treated in the wards of the hospital. In 1866 it opened its doors for accidents and all sorts of cases—medical, surgical, and gynaecological. It now possesses isolation wards for the reception of cases of infectious fevers, and so the safety from infection of the inmates of the general hospital and of the public who visit them is provided for. Within the last ten years the number of accident cases admitted into hospital has more than doubled, and the total number of patients attended to in 1893 was 12,000, in which were included 5000 accidents. The staff of trained nurses have been very successful and their services are eagerly sought for; and it is interesting to note that Sir Patrick Dun's Hospital was the first institution in the country to establish in 1867 and develop the modern system of skilled and efficient nurses which has conferred such benefits upon society at large. I heartily wish the promoters of the bazaar (Ierne) every success, and I am confident that some thousands will be added to the funds of a well-managed and most deserving charity.

Dublin Branch of the British Medical Association.

The eighteenth annual meeting of the Dublin Branch was

held last week in the Royal College of Physicians of Ireland. The report of the council was chiefly taken up with the condition of affairs in Cork between the medical profession and the benefit societies. A deputation from the Cork Branch waited on the council, and having explained how matters were the latter unanimously passed a resolution expressing their hope that the medical practitioners in Cork would maintain a united front against the attempt of the said societies to impose unworthy and inadequate terms on their medical officers. Dr. Atthill moved the adoption of the report, which was seconded by Dr. W. G. Smith, President of the Royal College of Physicians of Ireland, who said he was sure that the members of the branch would be unanimous in backing the action of the council in supporting the stand which the Cork and Southern practitioners had made against what would be an intolerable tyranny and an insufferable degradation to the profession.

Pharmacy Prosecutions in Dublin.

At the Southern Police-court last week the Pharmaceutical Society prosecuted a firm for having sold Fellows' Syrup, which contains strychnine, without it being labeled with the name and address of the sellers, in contravention of the Sales of Poisons Act of 1870. They were also prosecuted for retailing and dispensing poisons contrary to the Pharmacy Act of 1875. The defendants were fined £4 with £3 costs in each of three cases.

The Battle of the Clubs at Cork.

Dr. O'Sullivan took out summonses against two of the students who snowballed him, with the result that the magistrates, after a short consultation, dismissed the case against one of the accused and fined the other ten shillings and costs "for throwing snowballs." *Parturiunt montes, nascitur ridiculus mus.* On the counts were conspiracy and assault. The decision was received with loud cheers, which were renewed and renewed again until all the students had left the court.

Small-pox in Newry.

The epidemic shows no signs of abating, and there are 41 patients in hospital. All the deaths which have occurred, with one exception, were among those who had not been vaccinated at any time.

It is rumoured that Dr. Pye of Queen's College, Galway, has been offered the Presidentship vacant on the 24th prox. The post is worth £1200 a year with residence.

Dr. Glascott Symes died on the 17th inst. at his residence, 2, Gresham-terrace, Kingstown, aged eighty-five years. He was one of the oldest, if not the oldest, Fellow of the Royal College of Surgeons in Ireland. He practised for many years in Kingstown.

Feb. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Sale of Antitoxin.

SINCE the 10th inst. anti-diphtheritic serum is procurable only at druggists' shops, the price being marked on each wooden box enclosing the glass tube. A half tube (10 c.c.) costs 3 francs, and a full-sized tube (20 c.c.) 6 francs, 25 per cent. of this going to the druggist. Certain fussy and, it must be acknowledged, over-thrifty journalists having expressed their astonishment at any price at all being charged for a product towards the supply of which the *Figaro* collected from the public no less a sum than £24,000, Dr. Roux has condescended to furnish the following explanation of this very reasonable step. Part of the sum above mentioned was first devoted to the purchase of 100 horses, which are now located at Garches. The keep of each horse involves an annual outlay of 1000 francs, thus making 100,000 francs, or £4000, for the entire stand. A 5 per cent. interest on the capital of 600,000 francs would yield only 30,000 francs a year, leaving a deficit of 70,000 francs to be made up by the sale of the serum. But no fewer than 50,000 doses of serum have been gratuitously distributed. Now, as each dose costs the Institute 6 francs, it follows that 300,000 francs have been given away. Nor must it be forgotten that the hospitals, *bureaux de bienfaisance*, &c. will continue to be supplied gratis with serum. With these considerations in one's mind, how can a

reasonable being expect the whole supply of serum manufactured at the Pasteur Institute to be given away?

The Activity of the Paris University.

The total number of students inscribed in the various Faculties of Paris (law, sciences, medicine, &c.) was for the year 1894 12,325, as against 11,914 in 1893. The number of examinations undergone was 8340 at the Faculty of Medicine, as against 6064 at the Faculty of Law, 8108 at the Faculty of Sciences, 11,000 at the Faculty of Letters, and 1951 at the School of Pharmacy. The number of readers at the Library of the Faculty of Medicine was 158,754 and the number of volumes lent 275,000. At the School of Pharmacy the corresponding figures were 16,605 and 76,813 respectively.

Paris Sausages and Horseflesh.

The Comité d'Hygiène tells us that an inquiry recently conducted reveals a greatly increased consumption of horseflesh in Paris. Thus in 1892 there were killed for this purpose in the Paris abattoirs no fewer than 20,000 horses; but it must not be supposed that all this horse meat was sold by the 120 horse butchers found in Paris. The larger portion serves for the manufacture of sausages. Now the sanitary inspection of the abattoirs of Paris is so conscientiously conducted that it may safely be said that not a particle of horseflesh is exposed for sale that has not been carefully examined by a capable veterinary authority. The increasing popularity of the horse-sausage impelled the Syndicat de la Charcuterie de Paris to demand a compulsory declaration of the nature of the meat used for this purpose. But the difficulty was how to distinguish between the *chevaline* and the ordinary contents of sausages. Now it would appear that, thanks to two German investigators, MM. Edelmann and Brautigam, the problem is solved. The meat is thoroughly chopped up and boiled for thirty to sixty minutes in four times its weight of water. The bouillon thus obtained has added to it, after cooling, 5 per cent. of commercial nitric acid, and it is then filtered through paper. A few cubic centimetres of the filtered product are poured into a test tube, and a few drops of iodised water (saturated while hot) are allowed to flow down the sides of the tube. With the horse bouillon there is formed a violet-red-brown ring which is not developed in veal, beef, mutton, pork, dog, or chicken bouillon. The hot saturated solution of iodine may be advantageously replaced by Gram's solution, which yields a more pronounced colouration. The Comité d'Hygiène has, therefore, determined to give satisfaction to the Syndicat, and henceforth horse sausages will be labeled accordingly.

The Sore-throat of the Menstrual Period.

M. Raymond Petit¹ is disposed to consider the above curious ailment an outcome of the local activity of the streptococcus. He points out that although the prognosis is generally good an abscess may develop or erysipelas of the face appear. He recommends the use of antiseptic napkins during menstruation, and would have every menstruating woman employ systematically antiseptic gargles and mouth washes, woman constituting during her genital periods (accouchement, menstruation) a favourable medium for the growth of the streptococcus. I may add in support of M. Petit's contention that having recently to attend a young English girl for sore-throat during the menstrual period I succeeded in cultivating in serum colonies of the streptococcus, no other micro-organism being present.

Death of Dr. Dujardin-Beaumez.

This morning the largely attended funeral service of the above well-known physician took place at the ancient church of St. Germain-des-Près. This distinguished therapist died on the 15th inst., aged sixty-two, at Beaulieu-sur-Mer (Alpes-Maritimes), where he had gone to recruit his shattered health. I hope to be able to give next week a résumé of his scientific career.

Feb. 19th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Health of Leo XIII.

THE issues depending on the Pope's health are indeed momentous; his demise would bring to the front a question which has lain undisturbed since 1523. That year was the last in which a non-Italian Pope sat in the chair of

St. Peter; but for some time it has been seriously considered, in Italy as well as abroad, whether a departure from what is only consuetudinary law might not be taken. That a French, an Austrian, or a British cardinal might succeed to the Pontificate has but to be suggested to open up a battlefield of international jealousies. With this in prospect the wish that Leo XIII. may "see the years of Peter" or live to those of Pio Nono is sufficiently intelligible and explains the almost feverish anxiety with which reports as to his health are scanned and discussed. On Dec. 15th, 1894, I announced in THE LANCET the precautions taken by Dr. Lapponi in presence of the catarrhal symptoms under which His Holiness was labouring. On the 2nd inst. I described the return of the same symptoms between Jan. 10th and 16th, and to-day I resume the thread, *a titoli di cronista*, as Italians say. On the 10th inst., after celebrating mass in his private chapel before some twenty privileged persons, His Holiness held no audience, but retired to the seclusion of his apartments. He felt weary and worn out, and certainly looked more emaciated than usual. For some days previous the catarrhal symptoms, never wholly got rid of, had become aggravated, and his voice even on the 10th was still feeble and hoarse. Shortly before, during the religious function for the anniversary of Pio Nono's death, his exhaustion was manifest—his chanting the prayers of absolution being scarcely audible by those at a few paces from him. Dr. Lapponi is most vigilant as to the heating of the Pontifical apartments, and, on finding that the temperature had been raised above what His Holiness could bear with comfort, reduced it at once to a less relaxing degree. But with all his vigilance and authority it seems impossible to restrain the Pope from over-exertion, mental if not physical. He revels in work, and keeps in personal touch with high-placed ecclesiastics, Italian and foreign, and with the heads of the various Catholic congregations; while even at night he labours indefatigably in preparing documents for the guidance of his representatives in the two hemispheres. Such energy displayed by an octogenarian suffering from senile anemia and subject to a catarrhal cachexia increases the responsibility of his body physicians and quickens the anxiety of the diplomatists accredited to the Holy See, knowing as they do that in the event of the Pope's decease the fact will be kept undivulged till the cardinals present in Rome have completed certain acts preliminary to the Conclave—acts prescribed by a secret Bull issued four years ago by Pope Leo himself.

Cold and Famine.

The severity of the season has told heavily, particularly in the rural districts, all through Italy. A fuel famine has followed the food famine, and almost within the gates of Rome have been deaths from sheer cold accelerated by malnutrition. At Sambuci in the Sabine country the villagers have been subsisting on herbage and weeds, and even if wholesome food is forthcoming they have no fire with which to cook it. Too wretched and improvident to face any such visitation, the *adscripti glebæ* of Italy succumb to their fate with the helpless, hopeless submission of the fatalist, and, as at Sambuci, leave it to the chance-comer in their neighbourhood to reveal their misery to the great world. Since the confiscation of the conventual and monastic houses by the State the charity these used to dole out in their respective localities has had no adequate equivalent, and Parliament seems too engrossed with its own internecine quarrels, when not voting subsidies for Abyssinian campaigns, to attend to the far more pressing duties within its legitimate jurisdiction. Those contrasts are not hopeful for the Italy of the future, and the apathy of the upper and middle classes of the population must be replaced by a "sense of citizenship" if the country is to assert its claim to be a Great Power.

Death of Dr. Francesco Ziliani.

A striking personality has just left the stage in Dr. Francesco Ziliani of Brescia, one of Garibaldi's Thousand, who with Drs. Ripari and Boldrini constituted the sanitary corps of the romantic expedition which liberated the two Sicilies. Like Bertani, the General's body surgeon, whose *Codice Sanitario* has rehabilitated the public health of Italy, he was a man of austere virtue, carrying into public and professional life those moral standards to which he had conformed during the long years of silent preparation in the study and active service in the campaign. Italy is losing rapidly the few survivors of that heroic generation, and Dr. Ziliani's death on the 13th inst. makes her all too appreciably a man the poorer.

Obituary.

JOHN WHITAKER HULKE, F.R.S.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

It is a singular and melancholy coincidence that in so short a space of time as fifteen months the titular heads in this country of the two branches of the art of medicine should have died in office. It is but fifteen months since we chronicled the death of Sir Andrew Clark, which occurred on November 6th, 1893, during his tenure of the Presidency of the Royal College of Physicians of London; and now the medical profession not only of this country, but of all countries, has learned with deep concern of the death of Mr. Hulke, the President of the Royal College of Surgeons of England, and senior surgeon to the Middlesex Hospital. The coincidence to which we have referred is accentuated by the curious fact that Sir Andrew Clark died on Mr. Hulke's birthday.

There are some men whose lives are the despair of their biographers, but this is not generally the case with the distinguished surgeon. Widely read the surgeon often is, cultured it is now the rule that he must be, but his scheme of life, the issues that he has at stake, the work that he does, and the work that he hopes to do are not usually complex, so that his public life is wont to be comparatively easy to write. It consists of a record of duties performed whose value is estimated by comparison with the performances of others. But this is not so in the case of Mr. Hulke. For Mr. Hulke was a many-sided man, so that to estimate him properly more than a mere regard to the particular eminence to which he attained in his branch of the science of healing is required. Viewed as a surgeon Mr. Hulke had a career of singular distinction as well as of wide range. But he was also one of the first geologists in England. He was a real linguist—one with the gift of tongues. While keeping up a more than ordinary acquaintance with the classics, he was a fluent and accurate French and German scholar, a learned Shakespearian, and possessed at the same time of a working knowledge of Italian. He was a first-rate botanist, both in lecture-room and field—as may sufficiently well be seen from the opening half of the Hunterian Oration, which we print in our issue to-day, but which his health did not allow him to deliver. He was a sportsman of the old-fashioned sort, making his pursuit of the prey with rod or gun subservient to his desire to acquire accurate knowledge. And he had acquired it to this extent, that he was a distinctly learned ornithologist. He was an excellent diagrammatic artist, painted in water-colours, and was not unskilled in plastic work. As we have said, it is not easy to write a biography of such a man, for he excelled in so many directions that to narrate them all must give to his biography an appearance of fulsomeness.

John Whitaker Hulke was born on Nov. 6th, 1830, being the elder son of a well-known and widely respected general practitioner at Deal. The original family name was Hulcher, his ancestors being Dutch by origin, who had escaped from Holland during the Spanish persecutions under Philip II. and Ferdinand, Duke of Alva, and settled on the Kentish coast. There for some two hundred years they have followed the vocation of medicine. He was educated at

King's College School, and after a sojourn in Germany entered at the age of nineteen the medical school of that institution, where he was dresser to Mr. (afterwards Sir) William Bowman, and house surgeon to Sir William Fergusson. It was while he occupied this position that he attended the Duke of Wellington in his last illness, his father being the Duke's regular medical attendant and obtaining leave to avail himself of his son's services as assistant. In 1854, when the Crimean War broke out, he was early to volunteer, and at the beginning of 1855 was appointed assistant surgeon to the British Civil Hospital at Smyrna. Thence he was sent to Sebastopol, and in that awful campaign of irremediable sickness, gross mismanagement, and gallantry as often as not ineffective, bore himself in the opinion of everyone as a soldier should bear himself. On his return from the East he became medical tutor of King's College Hospital, and having previously been made a Fellow of the Royal College of Surgeons of England was appointed in 1858 assistant surgeon to Moorfields Hospital, and in this early devotion to ophthalmology we can trace the influence of his distinguished master, Sir William Bowman. He had previously been elected assistant surgeon to King's College Hospital, under an absurd arrangement by which the term of office of the assistant staff was limited to five years. He duly served his allotted period, and was appointed, together with Murchison, a colleague at King's, to the Middlesex Hospital, of which institution he was the senior surgeon at the time of his death.

Such is the bare outline of Mr. Hulke's career as a surgeon; we now propose to consider this a little more in detail. His earliest mark was made in ophthalmology. He obtained the Jacksonian Prize of the Royal College of Surgeons of England for an essay on the Morbid Changes of the Retina; his treatise on the Use of the Ophthalmoscope, published as far back as 1861, formed an excellent introduction for most of the profession to the new system of intra-ocular examination; his *Arria* and *Gale* Lectures delivered before the Royal College of Surgeons of England, and subsequently published in our columns, dealt with the Minute Anatomy of the Eye; and, lastly, he was made a Fellow of the Royal Society in recognition of the value of his papers on the Anatomy of the Retina in Amphibia and Reptiles. But although

JOHN WHITAKER HULKE.

so highly and widely recognised as an authority on the eye, Mr. Hulke was no less esteemed by the profession as a general surgeon, and the record of his work in the wards of Middlesex Hospital remains a monument to his skill and patience. There are no brilliant departures associated with his name, but he was absolutely painstaking and wise, and quick to see what surgical movements would stand the test of time. He was a supporter of aseptic doctrines at a time when many surgeons of his date were but half converted to these doctrines, and he was to a certain extent a pioneer in cerebral surgery, though all the teaching of his masters must have biased him to look upon interference with the brain as a very serious matter. As an operator he was not showy, and perhaps not entirely free from the imputation of being a little slow, but he was admirably careful, and his intimate anatomical knowledge counted for something in the marked caution of his procedure. As a clinical teacher he had few, if any, equals in London. He was lucid, learned, and simple. Where a point required exposition he was certain to know everything that could be said, but he was never tempted into needless display of erudition, and never talked for talking's sake. He was a little intolerant of ignorance in his pupils, but the idlest and most irreverent student always saw in him a man who had a right to be intolerant if he chose.

We have briefly referred to Mr. Hulke's knowledge of botany, but his position as a geologist merits more extended mention. He was one of the first authorities in the world on vertebrate palæontology, and contributed many valuable papers dealing with the Iguanodontia, Ichthyosauria, and Crocodilia to the memoirs of the Geological Society. For three years, from 1882 to 1884, he was President of the Geological Society; in 1887 he received the Wollaston gold medal, which is the highest award it is in the power of the society to bestow; and in 1890 and 1891 he acted as the society's foreign secretary. He has left behind him a large collection of specimens, mostly excavated by his own hands from the Undercliff in the Isle of Wight.

Few men have held more official posts than Mr. Hulke. At the time of his death he was President of the Clinical Society of London. It may not be out of place to repeat here the words of the retiring President, Sir Dyce Duckworth, when inducting his successor: "You have elected to-night as my successor one whom we all respect and acknowledge as a master of the surgical art, one whose modesty, rectitude, and fearlessness are only equalled by his skill and kindness of heart. Mr. Hulke will, I feel sure, add lustre to the post he comes to fill." From 1886 to 1887 he was President of the Ophthalmological Society, and he had also been President of the Pathological Society of London, and had been for many years, and was at the time of his death, librarian of the Royal Medical and Chirurgical Society. He was elected President of the Royal College of Surgeons, England, in 1893, in succession to Mr. Bryant, having been a vice-president from 1888. He was a member of the Court of Examiners for ten years from 1880. His greatest work in connexion with the Royal College of Surgeons was undoubtedly the formation of the Research Laboratory of the Conjoint Board. The scheme for this was Mr. Hulke's, and he was chairman of the Joint Laboratories Committee from its foundation. The work that has been done and is now doing there speaks sufficiently for the wisdom of the scheme. At the Royal Society—of which he was elected a Fellow in 1867—he served on the Council during 1879, 1880, 1888, and 1889; and was also a member of the Scientific Relief Committee. His communications to the Transactions of the society were numerous, and the last of them was read before the society on May 12th, 1892. It was a paper on the Shoulder-girdle in Ichthyosauria and Sauropterygia, in which he controverted the views of Professor H. G. Seeley.

Such was his arduous and many-sided work, and on all of it he brought the same qualities to bear—punctuality, the prudence of critical insight, and extreme conscientiousness. As a hospital surgeon he was always in attendance, always in time, and always thorough in his ward work. At the College of Surgeons he was never known to miss a lecture or to be a minute late. He attended every sub-committee and with unflinching punctuality. He was a man of very strict character, exhibiting not infrequently an austerity that amounted to harshness. Deeply religious, his Protestantism was of an intolerant kind; and of a relentless probity of character, his judgments now and again seemed unnecessarily severe. Yet many knew that he had another side to his character, and that, in addition to the rectitude and energy which gained him the universal and marked esteem of the whole profession, he possessed softer and more endearing qualities. He was exceedingly gentle and sympathetic with his patients, never for a moment lapsing into the attitude of the operator towards the subject. His acts of great personal kindness were numerous and his charitable desire to do good undoubted. We came into contact with Mr. Hulke in the matter of charity not infrequently, as he acted as an Almoner to our Relief Fund, and we know him to have been deeply alive to the needs of his poorer brethren, and most earnestly anxious to relieve them.

His strict standard of duty for others he held up to himself, and devotion to duty was doubly answerable for his death. He took no holiday during the past year, his time being too occupied to permit him to do so, and the incessant and acute strain was telling upon him at Christmas. This much he admitted. On the night of Thursday, Feb. 7th, a terribly bitter night, he was summoned to the hospital to operate upon a case of strangulated hernia, from which he did not return until 3.30 A.M. On the following day he had a little bronchitis, but did not keep his bed. Indeed, he operated on Saturday at the Middlesex Hospital on a case of cerebral abscess, and went to the wards again on Sunday (Feb. 10th) and Monday (Feb. 11th). But later in the day he had to recognise that he was seriously ill, and the bronchitis

increasing, pneumonia supervened, and he died on Tuesday, Feb. 19th, about noon.

Mr. Hulke leaves behind him no children, but a widow, who, we regret to learn, is suffering from a serious attack of influenza, and two nephews, one of whom is a member of the profession.

A special meeting of the Clinical Society of London was held on Wednesday evening last to consider arrangements necessitated by the lamented death of the president of the society. The following resolution was passed, and a copy of it forwarded to Mrs. Hulke: "The Council of the Clinical Society of London has learnt with deep regret of the death of the President of the Society, John Whitaker Hulke, F.R.S., one of its original members, among its most earnest supporters, a highly gifted and very learned surgeon, who has filled the office of president with his wonted punctuality, urbanity, and zeal. The Council begs to offer its heartfelt and respectful sympathy to Mrs. Hulke in her great sorrow."

The interment will take place to-day (Saturday, 23rd) at Deal. A memorial service will be held at St. James's, Piccadilly, where the late Mr. Hulke was churchwarden, on the same day at one o'clock.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. A. L. Loomis, Professor of Medical Pathology in the University of New York.—Dr. Sancho Martin, Professor of Midwifery in Valladolid.—Dr. Regnaud, Honorary Professor of Medical Chemistry in Paris.

THE INDIAN MEDICAL CONGRESS.

THE SECTIONS.

MEDICO-LEGAL MEDICINE.

DEC. 26TH, 1894.

THE HON. W. R. KYNSEY, C.M.G., F.R.C.P. Irel., delivered his presidential address. After a few introductory remarks he said: "The title of the Section sufficiently indicates its scope and object, and all here will agree with me that there is no branch of our profession more neglected than medical jurisprudence. Its history in Europe and the East, while full of great triumphs, is also full of cases where most serious consequences resulted from inexperience and ignorance, due to the fact that few make the scientific questions involved the subject of definite and intelligent study. To no science are the remarks of Ruskin more applicable: 'The greatest thing a human soul ever does in this world is to see something and tell what he saw in a plain way. Hundreds of people can talk for one that can think, but thousands can think for one who can see.' In the relations which exist between medicine and law the testimony of experts is necessary for the purpose of arriving at truth, which is the ultimate object of the medical and the legal professions, a trial being merely a means for obtaining it. The interest of good government, the sacredness of human life, and the welfare of man demand that no one should be accepted as a medical witness who has not made a special study of the many sciences upon which medical jurisprudence is founded. Medical evidence is important in all countries, but in the East it is often the only evidence at all to be relied upon, and on it alone often hangs the liberty or life of a human being."

[Mr. Kynsey then drew attention to the increase in all countries of communications dealing with criminology and continued:]

"The term 'criminal anthropology' was first given by Lombroso to that branch of morbid psychology which is concerned with the study of the physical and psychical peculiarities found in criminals, and it deals with all the problems connected with the criminal as he is in himself and as he becomes in contact with society. He maintains that by its means it is possible to determine the probability of a prisoner's reformation and the best methods by which this can be effected; but it cannot, of course, be used to discover the author of a crime, although by means of measurements prisoners can be easily identified accurately." He next quoted how criminals had been classified by Benedikt upon a pathological basis, and by Enrico Ferries upon a clinical basis.

"The Italian school, and those who think with them, consider criminality from a scientific point of view, and assert that it is a neurosis originating either in an inherited or an

acquired condition of the brain, which may be actual disease resulting in degeneration, or the non-development of certain faculties, the existence of which would preclude the possibility of crime. Criminality is a sign of physical degeneration of the nerve centres, and crime its outward expression. Crime is not, then, the result of personal spontaneity, but springs from the secret forces of organisation, and is a symptom of moral alienation due to inherited vice of character over which the criminal has no more control than the lunatic. They answer the question, Why is a man a criminal? by replying: For the same reason that another man is a moralist or an honest, law-abiding citizen. A criminal inherits a brain incapable of generating moral faculties, or through the influence of his environments his mind does not evolve sufficient moral strength to control his appetites and passions. It is no more difficult to believe that brain development in the evolution of mind may stop short of completely unfolding the moral faculties than it is to believe that it may, as it certainly does in many cases, stop before high intellectuality is attained. Whether a man will commit crime at all will depend to a great degree on his constitutional characteristics and education, and the nature of his crime on his environment and inherited tendencies, or on both. It is difficult to say how much can be attributed to heredity and how much to environment, as the fall from virtue to vice in anyone is possible; but the number of healthy, carefully brought up children who adopt a career of crime is very small and such cases are generally curable. The habitual and instinctive criminal, on the other hand, comes from a family in which inebriety, insanity, and criminality are hereditary, and whose members are surrounded by physical and social defilement. As there are anomalies, monstrosities, infirmities, and natural imperfections in the physical and intellectual world, there are the same in the moral, and the criminal differs physically, mentally, and morally from the honest member of society as much as the imbecile from the genius."

[Mr. Kynsey referred to Maudsley's account of the characteristics of the criminal class, adding some remarks of his own upon the physical and mental peculiarities of the criminal, and proceeded:]

"The criminal is not necessarily diseased, but there generally exists a latent neurotic bias, if not actual neurotic disease, such as epilepsy, inebriety, or insanity; and he is frequently scrofulous or tuberculous, all indicating nervous and bodily degeneration. Mentally he can reason about the crimes committed, but he cannot comprehend any moral wrong, and, conscious of punishment for past offences and almost certain of it for future ones, rushes wildly, heedlessly, remorselessly, into the vortex of criminality, and never pauses until the arm of the law interferes to protect society. Despine, in his exhaustive study of the criminal's mental nature, says: 'There must be something abnormal in the disposition of criminals when they yield with the utmost facility to desires which would excite the strongest repugnance and horror in a truly moral man. Does not this abnormal state reveal itself in the clearest manner when, contrary to what poets and moralists have represented, we see the wretch who has committed a crime exhibiting no symptoms of remorse, but rather a disposition to repeat the same criminal act?' He drew from this the conclusion that the criminal is morally insane, usually incurable, and that he should be treated in the same way as the intellectually insane person. The heredity of specific characters is a well-established fact, and the transmission of individual form or external physical characters, and even peculiarities, is universally acknowledged. The child resembles either the father or the mother, or both, or some member of the ancestral line, in general form, features, and even in the colour of the hair and eyes, the tint of the skin, and in general expression. Even deviations from the normal type are handed down through several generations, and may possibly establish new species. The functions of the organism, instincts, natural and acquired, the perceptive faculties through which impressions of the outer world reach the brain and are there converted into conscious sensations, memory, emotions, reason, will, the appetites, passions, and moral impulses, normal and abnormal, and the pathological conditions to which physical and mental life are liable are all capable of transmission under the laws of heredity from parent to offspring. 'Like begets like.' The hereditary character of crime was recognised in remote antiquity. Aristotle tells the story of the man who, when his son dragged him to the door by the hair of his head, exclaimed, 'Enough, my son; I did not drag

my father beyond this.' Inebriety, insanity, and crime are closely related; each is the result of a pathological condition of the brain, each is a stage in the progressive degeneration of a family, all are hereditary, and undergo mutual metamorphosis during the stages of transmission."

[Statistics were quoted in support of this statement.]

"I have endeavoured to show that many eminent writers look on crime as the result of disease of the brain, and in consequence advise the treatment instead of the punishment of this morally diseased class, and urge that the problem of prison administration is how to treat prisoners with the least burden to the community and at the same time secure ultimately the best advantages to the criminal. 'The prison is the battlefield between vice and virtue, with the advantage of position and numbers on the side of vice.' The modern school on this vexed question have no faith in punishment as such, but believe in correctional treatment, their motto being that every prisoner carries with him the possibility of good citizenship. Prison treatment should be, no doubt, both punitive and deterrent, but should also have for its object the permanent improvement rather than the deterioration of the prisoner's character; and unless goals are properly managed on these principles the State practically undertakes the criminal education of the dangerous classes. Crime can never be diminished through fear of punishment; and the benefits to be derived from the conviction and imprisonment of criminals increase in proportion as penal and retributive methods give place to more enlightened reformatory methods. In America from 60 to 70 per cent. of juvenile prisoners are reformed. The causes of crime have been most carefully classified under *cosmic*, such as climate and diet; *biological*, such as personal peculiarities, anatomical, physiological, and psychical; and *social*, which includes economic perturbations, alcoholism, pauperism, &c.; but the chief factors have always been and ever will be heredity—a vicious life, alcohol, a woman, a knife, and caste, race, and religious prejudices. If it is admitted—as it must be, I think—that every truly criminal act proceeds from a person who is temporarily diseased the older views on punishment will have to be considerably modified. As it has hitherto been directed at the offence, and it was not considered necessary to take the offender into account at all, the result has been most unsatisfactory, as statistics on the phenomena of recidivism prove, and the main cause of recidivism is the failure of prisons to act as reformatories. Laloue, the Inspector-General of Prisons in France, says: 'With our existing system twenty-four hours' imprisonment suffices under certain circumstances to ruin a man.' As to the reformation of the criminal,' remarks Dr. Paul Aubrey, 'that is a myth; the prison is still the best school of crime which we possess'; and a young Italian thief said, 'The houses of correction are much more houses of corruption.' In this place, for obvious reasons, I can only very briefly allude to the main proposals of prison reformers. They are: 1. To remove the belief that the criminal is an average human being, but to look upon him as an abnormal member of society, and to make the prison 'a moral hospital' for his treatment and cure. Sir Thomas Moore long ago said that the end of punishment 'is nothing else but the destruction of vices and the saving of men.' 2. To abolish the definite and predetermined sentence, and to substitute for it an indefinite one. This removes from the judge, who must be ignorant of the nature of the individual before him, the power of definitely fixing the period of confinement in prison, and transfers it to the managers of the reformatory, who have the power, if they see fit, to let prisoners out on *parole* (ticket-of-leave) at any time after a probationary period. 3. To improve the prison staff, under the belief that the prison warder of to-day is as little fitted for the treatment of criminality as the hospital nurse of half a century ago was for the care of disease. No one should be appointed to the care of criminals who has not been specially trained for the purpose. 4. To educate the criminal physically, mentally, and industrially, by means of skilled teachers, so as to win him back from the anti-social to the social world, and to give him when he leaves the prison a trade or means by which he can earn an honest livelihood. 5. To introduce a sound system for the identification and registration of criminals. The recognition of the habitual criminal is one of the most delicate and difficult functions of the police; they are blamed if they fail in identifying, and doubly blamed if they mistake an innocent person for the real offender. Both identification and registration can be accurately and unimpeachably carried out by the anthropometric system of

Bertillon. It is worthy of note that the Japanese have had for ages a system of prison treatment very similar to that which our most advanced thinkers now recommend. 6. To deal with the occasional criminal by substituting 'liability to punishment' for actual detention in gaol. This Section is not the one to deal with the question of prison mortality, as its consideration would involve a history of the diseases of prisoners and many other points; but as it is a subject of the deepest interest to all engaged in gaol administration in the East I may be permitted to make a few remarks. Writers at home are very fond of contrasting the death-rates of British and Indian gaols, to the detriment of the latter from want of knowledge. I am certain everyone who has had the management of prisoners in the East will allow that mortality in prisons depends largely upon:—1. The class of prisoner admitted, whether he is selected, the nature of his occupation in the free state, and whether he comes from a malarious or healthy district. The enormous influence of malaria in augmenting Eastern prison death-rates has not been taken sufficiently into account, and it is a curious fact that the removal of prisoners from malarious districts to healthy ones is often disastrous. 2. The discipline and nature of his labour in gaol. The stricter the discipline and the more continuously prisoners are made to work, even irrespectively of its amount, especially if never accustomed to work before, or if they are employed at work to which they were previously unaccustomed, the higher the death-rate. 3. Diet, whether there is change to unaccustomed food and whether it is too much or too little. 4. The early detection and treatment of disease. My experience is that, as well as malingering, there is a good deal of concealment of disease and actual indifference about health. If Eastern prisoners could be treated as the following extract shows they are pampered in England I have no doubt their sick and death rates would be as low:—'The early average death-rate for the 160 years ending March, 1878, was 11.6 per mille, while for the ten years ending March, 1888, it was 8.1. The Commissioners state that imprisonment as now generally conducted in England is a condition more or less akin to physiological rest. The struggle for survival is suspended and the prisoner appears to feel that the prayer for daily bread is rendered unnecessary by the solicitude of his custodians. Tranquility of mind and freedom from anxiety are leading characteristics of his life.' The second subject I wish to say a few words about is insanity. There never was a period of human history when insanity did not exist, and it would be strange if this were not so with the brain, the organ of mind, liable to have its development arrested, its functions disordered, or its action suspended, and the type of mental and nervous disease which exists in different races and ages is exactly that form which is in accord with their respective mental development—the most common in the savage is imbecility, in children idiocy. There can be no moral insanity where there is no moral sense, and no ideational insanity in infants because they have no ideas. The period of the world in which we live is characterised by an enormous increase in frequency of neurotic affections, due to the unparalleled activity and progress, rush and worry of modern life, a life of anxiety and high tension. The rapid cultural development of our time, gratification of ambition, change in the whole style of existence, strife of competition, and the desire to grow rapidly rich have made nations and individuals discontented. Insanity, like criminality, waits on civilisation, which Carlyle says 'is merely a covering underneath which the savage nature of man burns with an infernal fire,' and the reason for this is not difficult to explain, as there can be no doubt that there is an increasing complexity of the brain, the result of this higher civilisation, march of education, and struggle for existence, and, like all machinery, the more delicate its mechanism becomes the more liable it is to get out of order and the more difficult it is to readjust it. One melancholy evidence of the increase of insanity is the increase in number and size of the asylums which Christian benevolence and statesmanship have established for the custody and treatment of persons mentally afflicted. In Ceylon the admission-rate continues to increase, the percentage of recoveries on this rate being about 52 per cent., and the cases are of the usual mental types. The uneducated brain of the native is not usually roused to excessive fabrication of ideas even by insanity, his mental symptoms being more a monotony of noise, bad language, and filthy conduct. In all delusional cases the patients are persons of education. The causes are even more difficult to ascertain than in Western countries,

but all experience is against the influence of opium as an important factor in its causation, but there is no doubt about *dhany* being morally and mentally injurious. In a recent inquiry into the question with the Inspector-General of Prisons, we found no satisfactory evidence that the abuse of opium as distinguished from its use was on the increase, nor was there any evidence to show that the abuse of the drug has extended beyond a very small section of the community, and the admission to hospitals and asylums has not been influenced to any appreciable extent thereby. We were convinced of the enormous benefits which resulted from its judicious use, and we had reason to believe that a not inconsiderable portion of the drug imported was used in the treatment of animals; further, that any considerable diminution in its importation would involve a considerable increase in human and animal suffering. We were strongly of opinion that the use, even the abuse, of opium had not tended in any way to increase crime or insanity, though in certain cases it may have exercised an enfeebling influence over mind and body. As regards *dhany*, we found many cases on record in which it had been the immediate cause of crimes of violence, and we advised that its use should be restricted as far as possible by means of a heavy import duty and the prevention of its cultivation in the island. My belief is that natives who use opium have selected the least harmful form of stimulant—one which rarely acts as a cause of crime, insanity, or disease—and that any unwise interference will practically substitute alcohol, with all its dreadful immediate and remote effects, for opium. The agitation against it seems to be the result of ignorance. I have seen a few cases of that curious and dangerous condition known as 'running amuck,' or 'amok,' among Malays, due to *dhany*, and, perhaps, to opium. It is, no doubt, a transitory form of madness closely related to the *epilepsia cursiva* of Bhoottius, in which the person commences to run and then falls down in a fit. Wallace suggests 'that it is a resort to what appears to a savage to be a kind of honourable suicide on the part of a man who for some reason is plunged in sorrow and dejection, thinks himself wronged by society, or to whom on account of misfortune life has become a burden.' Trusting that my remarks have not been too long, and thanking you for your attention, I now give place to those who have prepared papers which we have all come here to hear read."

PROCEEDINGS IN SECTION.

DEC. 26TH, 1894.

The following is an abstract of a paper read at the Congress:

The Necessity for an Act restricting the Free Sale of Poisons in Bengal.

Surgeon-Captain J. F. EVANS, M.B., and Assistant-Surgeon CHUNI LAL BOSE, M.B., F.C.S., Chemical Examiners to the Government of Bengal, contributed a paper on the Necessity for an Act restricting the Free Sale of Poisons in Bengal. After a very carefully prepared introduction, in which they entered exhaustively into the prevalence of poisoning in Bengal and the nature of the cases of poisoning, and gave a general summary of the history of poisoning in India, they proceeded to consider their proposals for restricting the sale of poisons. After passing in review previous recommendations for restricting the sale of poisons and their outcome they continued:

"The measures we propose may be summarised as follows: (a) an Arsenic Act; (b) the amendment of those sections of the Bengal Municipal Act and Calcutta Municipal Consolidation Act which relate to the sale of drugs; and (c) the amendment of those sections of the Opium Act I. of 1878 which relate to the retail sale of opium."

The Arsenic Act.

[Surgeon-Captain Evans and Assistant-Surgeon Chuni Lal Bose here brought forward a table showing the imports and exports of arsenic at Calcutta during the last twelve years, and continued:]

"From the table it will be seen that a very considerable quantity of arsenic remains in the country. Last year the quantity was 30 tons. The fatal dose of arsenic for an adult is two grains. How then, some might say, is the poisoning by arsenic to be prevented, when it is such a deadly drug and when such large quantities are annually imported. But thirty tons are a small quantity compared with the 2875 tons which constitute the average annual output of white arsenic

at the tin works of Tavistock in Cornwall; yet fatal arsenic poisoning of a criminal kind is not as a consequence frequent in the neighbourhood of Tavistock. The larger portion of the arsenic imported into India is used in trade for such purposes as the cleansing and preparation of hides, paper, paint, wooden posts, &c., and occasionally also for agricultural purposes. The yellow variety of arsenic, which contains from 20 to 30 per cent. of white arsenic, is used as a pigment and largely as a depilatory. Without presuming that the proposition is complete and free from defect, or couched in the proper legal phraseology, the regulations of the sale of arsenic which we would propose take the following shape:—

"That certain individuals or officials shall be entrusted by Government with the duty of granting licences for the import, sale, purchase, and possession of arsenic, after having ascertained to their satisfaction that the applicants for such licences are fit and proper persons to be granted the same.

"That no arsenic or arsenical preparation recognised as a poison shall be bought or sold without a licence except on the prescription of a licensed medical man, with certain exceptions relating to the practice of indigenous medicine to be hereafter specified.

"That persons desiring to import arsenic into the country must obtain a licence authorising its import, and must undertake to keep the arsenic in safe custody and to sell it only to persons producing a licence authorising them to purchase arsenic, all such sales being registered with an entry of the date, the quantity sold, and the name and address of the purchaser.

"That dealers in arsenic, whether wholesale or retail, must obtain a licence authorising them to buy, sell, and possess arsenic; that they must undertake to buy from and sell to licensed persons only, and to carry on their business generally under the same conditions as the importers except in so far as its sale on medical prescription is concerned.

"That persons requiring arsenic for manufacturing and other purposes not being those of sale, retail or otherwise, must obtain a licence authorising them to buy and possess arsenic for such purposes, and must be prepared to satisfy the licensing authorities that they are fit and proper persons to be entrusted with the possession of arsenic, and that they are in a position to make suitable provisions for its safe custody both during use and at other times.

"That in rural districts, and, where necessary, in towns, the practitioners of indigenous medicine, if of good character, may be licensed to buy and possess a limited quantity of arsenic only in each year and to dispense the same to patients.

"That pounded white arsenic, except in special cases hereafter to be determined, be sold mixed with soot or indigo in the proportion of one ounce to each pound of arsenic.

"Amendment of those Sections of the Bengal Municipal Act and Calcutta Municipal Consolidation Act which relate to the Sale of Drugs.

"That the drugs named in the following lists, to be known as Schedule A, European Poisons, and Schedule B, Indian Poisons, be considered as poisons for the purposes of the Act:—

SCHEDULE A. European Poisons.

1. Arsenic and its preparations.
2. Mercury and its preparations.
3. Antimonial preparations.
4. Strong ammonia.
5. Strong acids, such as concentrated nitric, sulphuric, hydrochloric, and oxalic.
6. Phosphorus.
7. Hydrocyanic acid and cyanides.
8. Opium, its alkaloids and preparations.
9. Belladonna, datura, hyoscyamus, their alkaloids and preparations.
10. Nux vomica, its alkaloids and preparations.
11. Aconite, its alkaloids and preparations.
12. Hydrate of chloral.
13. Chloroform.
14. Carbolic acid.
15. Cantharides and its preparations.

SCHEDULE B. Indian Poisons.

1. White arsenic (Senko, Semul-khar).
2. Red arsenic or realgar (Monchhal).
3. Yellow arsenic or orpiment (Harital).
4. Corrosive sublimate (Raskarpura).
5. Aconite (Mitabishi).
6. Datura.
7. Hyoscyamus (Khorasani Ajwan).
8. Nux vomica bark or seed (Kuchila).
9. Plumbago rosea (Lalchitra).
10. Croton seeds (Jaipal).
11. Yellow oleander (Kolika).
12. Cocculus indicus (Kakumari).
13. Nerium odorum (Karubi).

"That in the same manner as suggested for the sale of arsenic licences be granted for the sale and possession of poisons.

"That except under certain conditions and in certain quantities, to be specified in each case, no poison within the meaning of the Act shall be bought or sold without a licence, except on the prescription of a licensed medical man.

"That persons engaged in the merchandise of poisons as defined by the Act must obtain a licence authorising them to carry on such business, and must undertake to conform with the provisions of the Act and not to sell poison in any quantity larger than that permitted for its retail sale other than to duly licensed individuals, except on medical prescription.

"That every sale of poisons except on medical prescription, with certain exceptions relative to the practice of indigenous medicine, must be duly registered in the following manner:—(a) Name of purchaser; (b) residence of purchaser; (c) object of purchase; (d) authority for sale; (e) quantity sold; (f) date of sale; (g) signature of the seller; (h) signature of the purchaser.

"That no person shall be permitted to buy and possess poisons who is unacquainted with their nature, and is not in a position to make proper arrangements for their safe custody and sale.

"That in the shops of individuals licensed to sell poison, the poisons are to be properly labeled with the name of the poison and the printed word 'Poison' both in English and vernacular, and kept apart from other articles of merchandise.

"That in rural districts and, where necessary, in towns, practitioners of indigenous medicine, if of good character, may be licensed to buy and possess and dispense to their patients limited quantities of the poisons included in Schedule B.

"That all practitioners of medicine licensed to prescribe or dispense poison be registered.

"That the same regulations should apply to persons requiring poisons for manufacturing and other purposes not being those of sale, as were recommended in the case of arsenic.

"That it may be advisable to permit a limited retail sale of certain of the poisons included in the schedules for domestic and other purposes, and that the drugs which may be sold, the quantities to be sold, and the manner of the sale be hereafter determined.

"That all patent and proprietary medicines, if found to contain poison within the meaning of the Act, come within the operation of its provisions."

Amendment of those Clauses of the Board's Excise Opium Form No. 1 which relate to the Sale of Opium.

The authors then went on to consider the question of the retail sale of opium. The present largest quantity of opium that may be purchased on any one occasion by any single private individual is 2 oz. They propose to limit this quantity to grs. xx. (20), and this limit would quite satisfy the average opium-eater.

"At the present time opium-eating is not to be regarded as a vice in any sense of the term, but only as a habit, the excessive gratification of which engenders very serious dangers to the community at large if it requires that large and fatal doses of opium must be sold without restriction. It is not too much to require of the opium-eater whose daily dose has exceeded the retail limit that he should provide himself with a certificate to that effect, signed by a medical man or a respectable individual such as the headman of his village. We would suggest that such certificates should state the daily dose required and should be valid for one year only, and that the opium vendor on the presentation of a certificate of this kind should be authorised to sell the quantity intimated therein, provided it does not exceed five tolahs. The proposed amendment of the Board's Excise Opium Form No. 1 is accordingly as follows:—

"That he do not, except to a vendor of opium or of an intoxicating drug licensed by the collector or to a licensed druggist, sell more than one-eighth tolah of opium to any person at one time except on the production of a certificate stating that the purchaser is an opium-eater, signed by a licensed practitioner of medicine or a respectable resident of the locality, when the quantity specified in the certificate, provided it does not exceed five tolahs in weight, may be sold.

"All sales exceeding one-eighth tolah to be entered in a special printed record, giving in addition to the information required in Paragraph XIV. of Form No. 1, the name and residence of the purchaser, the authority for the sale, and the quantity sold.

[They then proceeded to consider the difficulties attending the working of this measure, and continued:]

"Without attempting to raise the question whether the policy of temporising with an admitted evil is correct we would at once ask, What are the poisons which may be expected to take the place of arsenic, aconite, opium, and other controllable poisons if these are rendered more or less inaccessible? If any such exist, they must naturally be sought among the indigenous drugs of the country which belong for the most part to the vegetable kingdom. That the country has many vegetable products endowed with poisonous properties is easily learned by reference to the Pharmacographia Indica written by Dymock, Hooper, and Warden. Fortunately, however, the knowledge of the poisonous properties of the majority of these substances is not yet by any means popular. They may in consequence be considered rather as potential rather than actual poisons at the present time, so far as the people generally are concerned. As judged from general information and from all the cases of poisoning which are reported, the number of indigenous vegetable poisons commonly known is very small. The following are the chief: opium, datura, aconite, nux vomica, oleander, and abrus precatorius. Opium heads the list, and is responsible for more fatal cases of poisoning than any other drug; but, as already shown, its accessibility can be controlled without imposing hardship on those who require it for a legitimate purpose. Successful interference with the possession of datura is apparently hopeless. Fortunately, the uncertainty of its action is tolerably well recognised. It is in consequence ill suited to the murderer's purpose, as great risk of detection would be incurred should the poisoned man recover. The murderer does not of necessity desire to leave the locality of the murder; the robber, on the other hand, administers datura to assist him in the act of theft and to cover his flight with the booty. Datura poisoning is chiefly non-fatal. Aconite, like arsenic, is an imported poison, and though its introduction

into the country cannot be so easily controlled as that of arsenic, yet as the channels of introduction are well-known, a feasible plan to prevent the widespread dissemination of the drug shall be practicable. The physiological symptoms set up by the chewing of even a small fragment of aconite root are a bar to its frequent use as a poison, and have frequently assisted in the discovery of the poisoner. Nux vomica trees can hardly be said to grow wild in this part of India in the same way as datura. They are to be found here and there and have generally been planted for some purpose. Nux vomica seeds can, however, be readily purchased in the bazaar. One seed is sufficient to poison an individual, and one tree may produce many hundreds of seeds. As nux vomica trees are not numerous and do not grow wild, their cultivation, except in certain recognised places and by authorised individuals, should be prohibited. The cases of poisoning which arise from the use of oleander are for the most part accidental. The plant is to be found in most gardens and, like datura, it is a poison which cannot be removed from the reach of the poisoner. Its poisonous properties do not seem to be very widely known, and its action is somewhat uncertain. The method of using *abrus precatorius* has already been referred to. These, then, are the poisons which have been in use for half a century and more. The accessibility of three of them—viz., opium, aconite, and nux vomica—can effectually be controlled. *Abrus precatorius* is seldom used, and then only as a cattle poison. Datura and oleander remain, but their use (oleander for homicide or suicide) is rare now, for the reasons already given, and for those reasons is not likely to become more prevalent. It is, of course, very difficult, if not almost impossible, to foretell what altered conditions may bring about; but as for many years there has been practically no apparent attempt among poisoners to strike out a new line, it may reasonably be hoped that the introduction of a restricted poison sale would for several years enforce a sensible diminution in this class of crime. It is of some interest to note that so long ago as 1843 Dr. Mouat, then Chemical Examiner, considered that the use of vegetable poisons was on the increase, and wrote as follows: 'The great majority of cases of the administration of poison had hitherto been arsenic. Lately, however, the exhibition of vegetable poisons has been more resorted to from its being known to *hakims* and native druggists that while minute traces of any mineral poison can be unerringly detected, most vegetable substances defy analysis in the present state of chemical science. Some check ought to be put to the amount of murder committed in this way, unknown and unrecorded, by legislative enactment punishing all vendors of drugs in whose possession those substances are found.' Dr. Mouat's apprehensions have, however, proved groundless, for Dr. Warden, referring to this statement, was able to state in 1886: 'The above was written about forty years ago; the fear expressed that vegetable poisons might supplant arsenic has not been verified. Arsenic is still the homicidal and cattle poison of India.' It will naturally be advanced that from Dr. Mouat's time up to the present arsenic has remained easily accessible, and the necessity for discovering suitable vegetable poisons has not arisen. But even should the properties of indigenous vegetable poisons become generally known, these substances could never compete with arsenic in fitness for the poisoner's purpose. A comparison of the properties of arsenic and vegetable poisons as a class will at once indicate the advantages which attend the use of arsenic.

"Properties of arsenic and vegetable poisons generally:—

Arsenic.

1. Tasteless.
2. Certain in action.
3. The fatal dose is a small quantity.
4. Stimulates in a remarkable manner the symptoms due to natural disease.

Vegetable Poisons.

1. Acrid, bitter, or unpleasant taste.
2. Uncertain in action, due to the varying quantity of the active principles present in different specimens of the same plant.
3. To cause death larger quantities are necessary of the majority of crude vegetable drugs.
4. Do not simulate the symptoms of disease to anything like a corresponding extent.

"The certainty of its action, its want of taste, and the smallness of its fatal dose (two to three grains) require no further comment. They alone would give to arsenic a place in the front rank of the poisoner's equipment in any country. But the similarity of its symptoms with those induced by disease

gives it in India a special value which is well illustrated by the following case:—'On Oct. 28th, 1894, a man was admitted into the Mayo Hospital, Calcutta, suffering from symptoms of choleraic diarrhoea. He arrived alone and stated that he had come from Moorshedabad by steamer, having purchased and eaten food in the bazaar before leaving. He became ill on board the steamer. After admission his symptoms were attributed by one of the medical officers to arsenical poisoning, but by three others who also examined the patient from time to time he was considered to be suffering from choleraic diarrhoea. The man died on the fourth day after admission and a post-mortem examination was held. The condition found was one of general congestion of the alimentary canal with ulceration of the stomach and ecchymosis over the columnæ carnes of the heart. Portions of the viscera were sent to the chemical examiner for analysis which revealed the presence of arsenic.' It is legitimate to expect that many similar cases occurring in the district are returned without challenge as cases of cholera, if such a diversity of opinion can arise in a hospital provided with an experienced and expert medical staff. We have reason to believe, as already stated, that acquaintance with the vegetable poisons of the country and knowledge of their properties are not by any means widely diffused even among the rural population. On the other hand, it is, of course, quite impossible to determine what the practical knowledge of *hakims* and native druggists may be as regards indigenous vegetable poisons. In 1843 Dr. Mouat suggested that the *hakims* and native druggists were beginning to put their knowledge to a criminal use. Whether this holds good at the present time, and to what extent, we are quite unable to say. In towns the practitioners of indigenous medicine are as a class a respectable body of men. No doubt here and there black sheep are found among the *hakims* who are not over scrupulous as to the methods in which they earn money. But should the scheme proposed be put in force the *hakim* will be dependent for a supply of drugs very important if not essential to him in his practice upon the evidence of good character and conduct which he can adduce. In future the *hakims* would possess a definite status. A recognised position and the discharge of responsible duties are often sufficient to deter criminal instincts from the abetment or commission of crime. Without implying that the detection of a vegetable poison is as certain as that of a mineral, it may yet be confidently stated that the chemical methods for detecting vegetable poisons have considerably improved since the time of Dr. Mouat's report already referred to. And though there is still room for further advance in this direction much has been done, and vegetable poisons can be detected by chemical analysis of viscera with a very considerable degree of certainty as compared with the results of fifty years ago. Should resort to indigenous vegetable poisons be stimulated by restrictive measures it is probable that chemical research into the nature of these poisons and the best methods of detecting them would also be stimulated. Much has already been done in this direction by Dymock, Hooper, and Warden. If the proposed measures be carefully reviewed it will be seen that special cognisance has been taken of customs and habits, and the measure so drafted that no undue interference with habits and customs can arise. In the measures to restrict the general sale of poisons a special clause is introduced to legalise a small retail sale to unlicensed persons, the provisions of the clause to be hereafter determined. The practitioner of indigenous medicine will not be interfered with in his practice, but will be recognised and registered, and will, so far as the general community are concerned, become a more important, a more responsible individual than heretofore. We are aware that the proposal to register the practitioners of the province has already been once made and that it was abandoned on account of the difficulties of the task. We are now, however, approaching the matter from a different standpoint. It is utterly impossible to conceive of any scheme for restricting the sale of poisons unless a register is kept of those persons to be entrusted with certain privileges with regard to poisons. A licensed or registered medical practitioner is the only individual in most countries who is allowed to prescribe, sell, or possess poisons without challenge and without having to keep a list of the quantity of poisons prescribed and sold by him in the discharge of his duties. The obligation to register his name and address is a very small matter indeed in return for such important privileges, nor need the act of registration be made unduly vexatious. All medical practitioners in the employment of Government are already registered by

the Imperial and provincial Governments, and there would be no necessity to trouble them in any way. In Calcutta all practitioners of medicine have to obtain a licence from the municipality permitting them to practise, and this would simplify the registration of medical practitioners in Calcutta very greatly. In small towns and rural districts registration must of necessity be a very gradual process. It would follow on the exhaustion of the stock of poison in the possession of the practitioner of indigenous medicine and the necessity of obtaining a licence before it could be replenished. A measure of this kind can only very gradually be brought into force among a population such as that of the province of Bengal. Numerous difficulties would no doubt be encountered in its introduction, and the full measure of benefit to be derived from its operation would only slowly be realised. But, on the other hand, without some such scheme of registration the restriction of the sale of poisons seems impracticable. The interference with trade will practically arise only from restricting the free sale of arsenic. The value of the average annual quantity of arsenic imported into the country at the port of Calcutta during the last ten years has been about £308 sterling, valuing the arsenic at £14 per ton. The value of the average annual number of animals poisoned by arsenic in the province of Bengal only during the same period may be calculated as about £180 sterling. A certain amount of annoyance must of necessity be experienced in certain trades and occupations on the introduction of a restricted sale. It is possible that certain individuals who are now in the habit of using arsenic in their trade may be unable to obtain it in the future. Such objections should not, however, be allowed to carry any force. The convenience of the few can hardly have weight when the interests of a population have to be considered. Those persons who are fit to be trusted with poison will be able to obtain it under conditions of restricted sale as readily as at the present time. They will, however, have opportunities of realising that they are responsible for the safe care of the poison which they are permitted to buy. The value of the arsenic imported into the country at the port of Calcutta does not indicate that any important industry would be injured by the proposed measures.

"We have now reviewed those objections to the introduction of measures restricting the free sale of poisons which appear to us to be the most important. For many years past the introduction of such measures has been frequently recommended. It is trusted that the sketch given in our paper of the present prevalence and nature of poisoning in the province of Bengal may serve to demonstrate that the necessity still exists. Without under-rating the difficulties attending the introduction and working of such a measure incidental to the special conditions prevailing in India, we are confident that its introduction would be attended by great reduction in crime. We do not pretend that the measures proposed by us are free from defect or incapable of improvement. The scheme, such as it is, is submitted for criticism. In conclusion, we have to thank Dr. Simpson, health officer of Calcutta; Surgeon-Major J. B. Gibbons, police surgeon, Calcutta; Dr. Sasibhusan Ghosh, assistant to the health officer, Calcutta; Babu Mohini Mohan Chatterjee, attorney-at-law of the Calcutta High Court; and Babu Surendra Nath Mitra, B.A., registrar, Bengal Secretariat, for information and assistance in the preparation of the statistics contained in this paper."

SURGERY AND OPHTHALMOLOGY.

DEC. 27TH, 1894.

The following are abstracts of papers read in the Section of Surgery and Ophthalmology:—

Radical Cure of Inguinal Hernia at the Hospital of Pondicherry (French Colony).

Dr. HENRY GALLAY, Surgeon-Major of the Colonies, read a paper upon the Radical Cure of Inguinal Hernia at the Hospital of Pondicherry. He said:—

"In the two years that we have had charge of the medical service at Pondicherry we have performed in the hospital thirty-eight times the radical cure of hernia inguinalis. The number of the operated cases is only thirty-six because twice we have had to operate for hernia on both sides of the same man. Our operations have been made thirty-one times on

the right side and seven times on the left. Twelve times our hernias have been found complicated and our surgical operation aggravated owing to the necessity of performing at the same *séance*—twice the amputation of a cancerous testicle, twice the radical cure of old hæmatoceles, and eight times the radical cure of old and voluminous hydroceles. Twice we were in the presence of adhesions of the intestine with the hernial sac; it was impossible to extirpate these adhesions, and we were obliged to reduce the intestine from the bag, from which it was impossible to separate it. Three times we noticed that the cæcum came down in the scrotum. Once the cæcum was accompanied by the upper part of the colon and by a lump of epiploic fringes abnormally swollen; the lump once pulled off weighed nearly 4 lb. Another time we saw the cæcum and the ileo-cæcal appendicula ruptured on the left side. On another occasion we found the hernial bag adhering to a doubled fatty tissue three inches thick. Thus it is seen that out of thirty-six operations eighteen were complicated, or 50 per cent. Notwithstanding the disadvantages of such a series we had but four fatal cases—that is, 11 per cent. One of the fatal cases which we had to record was caused by tetanus. The local hospital, where we operate, was formerly the hearth of tetanus. During the last years, although we have carried out upwards of 300 surgical operations, it was the first time that terrible infection occurred, and perhaps we would have as much right to accuse the flesh of our patient as the locality where we operate. The man was a farmer, living in contact with the soil; perhaps the assistant in charge of the antiseptic arrangements had not sufficiently disinfected the field of operation. On one occasion the hernial sac was doubled with a real sort of web from which it was impossible to separate it; it was strangled by two pieces of catgut crossing each other and then reduced; the thickness of the fatty tissue was no doubt such that a small artery was insufficiently strangled. A small adhesion was formed on the right side of the iliac pit; the hernia was then on the left, fever set in, and the patient succumbed after presenting the symptoms of peritonitis. At the necropsy it was noticed that the neck of the bag, which was on the left side, had gone, after its reduction, to the right, and that around it a little hæmorrhage had taken place and had served as the starting point of the inflammation of the peritoneum. The third death was owing to the prolonged suppuration which occurred in an old debilitated patient on whom we operated on the same day for the radical cure of an inguinal hernia on the right side and an old hydrocele on the left side. There was no serious accident on the side of the hernia, only a few drops of liquid collecting under the suture. On the side of the hydrocele there was also a little running in the lower part of the scrotum, and when the surgical wound was cicatrised by first intention we were surprised to find at the inferior and posterior parts of the scrotum a large piece of flesh gangrened. The elimination of the slough caused a suppuration of long duration, from which the patient did not recover, succumbing on the seventeenth day after operation. The fourth and last death was that of an old man in whose scrotum we found, not only the cæcum, but the greater part of the large intestine, with 4 lb. of the epiploic fringes abnormally swollen. The reduction of that mass of large intestine, which had since long ceased to lie in the abdomen, was very painful. However, everything seemed to have taken place normally. In the evening, twelve hours after the operation, the patient was well. In the night the stomach swelled with extreme rapidity, and he succumbed with symptoms of asphyxia before we could be sent for. A post-mortem examination was not permitted. As we have finished relating our failures, we will now proceed with our successes. Twelve times we have obtained the ideal result—that is to say, reunion by first intention, ablation of the sutures on the eighth day, and complete cure on the nineteenth. As a precaution the patients were kept in bed until the thirtieth day, when they left the hospital. Twenty times cicatrization was delayed, either because the sutures have cut the flesh, or because under the superficial sutures a little liquid has accumulated, which it was necessary to allow to fill up the cavity which was formed for that purpose. In two cases we found the cords of the testicles swollen with a profound suppuration. The patients kept in the hospital under small surgical complications stayed generally forty-five days; two stayed forty-eight days and only two left on the fifty-third day. Authors are willing to admit that relapses after operations for hernia occur before the sixth

month. We have met fourteen of our patients, who were operated upon on the following dates:—

Date.	Months after operation.	Date.	Months after operation.
Dec. 19th, 1892	... 21	Dec. 17th, 1893	... 9
Jan. 25th, 1893	... 13	.. 20th, 1893	... 9
Sept. 17th, 1893	... 12	Jan. 29th, 1894	... 8
Nov. 6th, 1893	... 10	Feb. 12th, 1894	... 7
.. 10th, 1893	... 10	.. 23rd, 1894	... 7
.. 24th, 1893	... 11	April 23rd, 1894	... 6
Dec. 8th, 1893	... 9	.. 26th, 1894	... 6

Among all the recovery has been perfectly well kept up. Among all the scar is soft, and the inguinal cord free from adhesion, and what makes the whole of these results interesting is that among the patients one happened to be an old weak-looking man sixty-one years of age, in whom the cure of a long-standing large-sized hernia has been completed by the excision of a cancerous testicle. Having regained his plumpness and alertness, this old man, formerly an invalid, now walks easily, two years after operation. The next were four sepoys, three of whom after one month's rest—the first thirteen months, the other two ten months since—resumed their military duties and bore all the hardship of them. There were three police peons who for ten, seven, and seven months respectively have been patrolling night and day, and on their legs from six to eight hours a day. One patient was operated upon on Dec. 20th. While he was a scholar he left the hospital to enlist himself as a sepoy, and for ten months has been well enough to perform the military gymnastics and other hard work, and bears without difficulty the painful period of the young soldier's instruction. Two are Europeans: one a medical man on board the steamer, has, six months since, resumed his duty on board and goes up and down the ladder, and supports the necessary muscular efforts to struggle against the rolling and pitching, and that without wearing a truss. The other one is a tramp; he was operated on more than ten months ago for a hernia about the size of an adult's head. He recommenced his old roving existence, living on the roads, wandering barefooted from Cuddalore to Pondicherry, even extending his begging trips to Trichinopoly, without being tired or threatened with relapse. In all cases I made use of Bassini's process, which, as everyone knows, consists in the reconstitution, by means of two whips with catgut, of the two partitions of the inguinal channel in their full length, while the deep orifice of the channel retains just the width sufficient for the inguinal cord to pass through. The therapeutic results I have just related allow me to conclude as to the excellency of this method; it gives to the reconstituted abdominal partition a perfect stability, allows the inguinal channel to be free to let the cord to pass through, and by shutting the deep opening of this channel prevents all opportunity for a relapse. The busy and tiring existence which since the operation has been led by the two European patients, four sepoys, three police peons, and the young recruit confirms the conclusions which Bassini himself, when publishing his surgical method, formulated—viz., that as soon as an inguinal hernia has been successfully operated on, when the reconstitution of the partitions of the channel has been methodically made, the patient can be considered as completely cured, go through the most arduous professions, and no longer bear any bodily defect on account of which he could be rejected from the military profession or exempted from the military service."

Contagious Pemphigus.

Assistant-Surgeon SOORJEE NARAIN SINGH, Teacher of Materia Medica and Therapeutics, Temple Medical School, Bankipur, read a paper on Contagious Pemphigus. He said: "Pemphigus is described in text-books as a non-contagious skin disease. I have, however, seen cases which occurred one after another in rapid succession in the same family, as also by communication in neighbouring families. In August, 1893, while in consultation with Surgeon-Lieutenant-Colonel E. Bovill in a case of clubfoot in a new-born child, I noticed pemphigus on the body of that child. Surgeon-Lieutenant-Colonel Bovill suggested to me the keeping of a record of such cases as could be found to have occurred in the same family. Since that time I have had opportunities of seeing cases of pemphigus in three families in which it affected several children in quick succession. In Family 1 there were seven cases, all occurring within a period of from Aug. 5th to 20th, 1893, and in children aged from fourteen days to six years. In these cases the bullæ varied in size from a large pea to a hen's

egg, containing a clear fluid which gradually became opalescent. Some of them burst in a day or two, sometimes earlier. In those that burst the cuticle would curl up, in places, exposing the red, raw surface underneath and forming a slightly yellowish crust. In those that did not burst the cuticular wall shrivelled up, forming a thin white crust, which in a short time withered away. The mark left on the body would be a faint pink white in colour for a few days, but afterwards there would be no trace whatever on the skin. There would be no pit or cicatrization. In the cases I examined I found that no sooner was one set of bullæ on the decline than another set would crop up, and so forth, for a week or two, sometimes extending to three weeks. The bullæ were all separate and none of them coalesced. The eruption at first appeared as small red spots, which rapidly formed into blebs. The bullæ were generally found on the hands, legs, and back. There was little or no fever, only a slight constitutional disturbance being present, such as loss of appetite, slight emaciation, and general uneasiness, probably from the pricking and smarting pain of the bullæ. In Family 2 there were three cases of pemphigus, also occurring in children aged from eleven months to seven years, and within a period extending from Sept. 10th to 26th, 1894. All these cases were of a similar nature to those in the foregoing family. In Family 3 there were two cases occurring on Oct. 19th and 29th, 1894, and in children aged two years and two months respectively. It is a remarkable fact noticed even by the lay members of the house that one of the three children of Family 2, the one aged eleven months, had been brought by her mother to the house, and a few days after the child aged two years of Family 3 (who in all appearance was a very healthy girl) was affected. This case was exactly similar in nature to those described in Families 1 and 2. The second case of this third family was, however, of a very grave nature and terminated fatally. The little infant, aged two months, had only been under homœopathic treatment for diarrhoea. When I was called to see it I found a big bladder filled with clear serum on the upper part of the abdomen, extending from the splenic to the hepatic region, and breadthwise from the epigastric to within an inch above the umbilicus. There were big bullæ also on the groins, the chin, back, arm, legs, and ankles all rapidly distending themselves and bursting, the surrounding skin remaining perfectly healthy. The child was in great agony, constantly crying; the fever was high—viz., 103° F. Some of the bullæ had burst, exposing the red corium. The discharge from the bullæ was of a fetid smell. In short, the child looked, as it were, scalded all over. It had been in a bad state of health from birth, suffering repeatedly from indigestion and diarrhoea. On the whole, if I am to analyse all the cases I saw during the last two years I am inclined to think that pemphigus, at least in the certain forms I have had opportunities of examining it, is of a contagious nature. In family No. 1 and in family No. 3 the disease could be traced to have occurred by communication with persons suffering from the same disease in the neighbourhood, whilst in the same family it spread amongst the children very rapidly. I cannot say that the disease could be in all these cases the result of a certain condition of the system, such as are occasioned from bad health or insanitary living. The cases I examined were, although not models of health, yet except one quite as healthy as native children ordinarily are, and living in houses and localities not particularly insanitary. While I was examining my cases I had my eye open regarding any mistake as to diagnosis. I was sure my cases could not be mistaken for a varicella. Even the smallest bullæ were larger than any varicella vesicle, and the large bullæ or the bladders in my cases have no comparison in varicella. The succession of crops of bullæ in the cases I examined continued to two or three weeks, whereas in varicella there is generally no fresh crop after a week. In varicella there is always left in the skin for a considerably long time a whitish blue stain, which may also be pitted or cicatrised. In my cases, after the cuticular wall crumbled, there was no pitting, and the pink white skin left, lasting only for a few days, would leave no mark whatever. In varicella, again, there is often an ulceration before cure. In my cases there was no ulceration, except in one pemphigus gangrenosus. My cases could not also be mistaken for varicella bullosa, because they had rapidly enlarged and fully distended before bursting; whereas in varicella bullosa the vesicles do not generally enlarge until they have burst, and they generally enlarge at the periphery of the crust. There was no case of chicken-pox in the neighbourhood at the time I saw the cases

of pemphigus. I find the question whether pemphigus is or is not contagious has of late attracted the notice of some medical men in Europe; and, in conclusion, I beg to apologise for making any assertion contrary to the teachings of the text-books, but I leave my experiences to the Congress with a view that the question may be investigated."

Medical News.

UNIVERSITY OF LONDON.—The following candidates passed the Preliminary Scientific (M.B.) Examination in January, 1895:—

ENTIRE EXAMINATION.

FIRST DIVISION.

Keays, Lionel Francis, St. Paul's School and private tuition.
Kelly, Charles Ernest M., Owens College.
Manson, Patrick Thurburn, University Tutorial College.
Oswald, Felix A. Clair, B.A., private study.
Petch, Tom, B.A., private tuition.
Shopland, Thomas, B.A., University Tutorial College and private study.
Vernon, Ethel Miller, University Tutorial College.

SECOND DIVISION.

Coffin, Arthur Charles, B.A., private study.
Davies, David Leighton, private study and University Tutorial and University Colleges.
Easton, Harold Augustus, private study and University Tutorial College.
Ehrlich, Henry Albert, Owens College and private study.
Hoban, Thomas, private study and St. Thomas's Hospital.
Jarvis, George Charles, B.A., private study.
Jones, Wm., Henry Pryce, B.A., private study and University College, Liverpool.
Kevern, Samuel, B.A., Plymouth Technical School.
Raven, Eustace, St. Thomas's Hospital.
Ruckwood, David Pratt, University College and Gower-street Laboratory.
Smith, John Salmon, University College.
Spilsbury, Bernard Henry, Owens and University Tutorial Colleges.
Trumper, William Arthur, St. Mary's Hospital.
Woodcock, Louisa, University Tutorial College.

CHEMISTRY AND EXPERIMENTAL PHYSICS.

*Aldred, John White, Owens College.
Armitage, John James, School of Science, Cheltenham.
Beaumont, Noel Charles, St. Bartholomew's Hospital.
Beensley, Vernon Cyril, St. Mary's Hospital.
*Bernard, C. Constance, private tuition.
Billinghurst, Walter Brinsmead, Merchant Taylors' School.
Blythe, Thomas Thompson, University Tutorial College.
Boissière, Felix Anthony, King's College.
*Brown, Charles Richard, St. Bartholomew's Hospital.
*Burn, William Leopold, private study.
*Capper, Harold Selwyn, private study, and University Tutorial College.
*Dawson, William Collings, King Edward High School, Birmingham, and Mason College.
*Drake-Brockman, Henry George, University Tutorial College.
Ede, Alfred Gordon, Durham College of Science and St. Bartholomew's Hospital.
*Etheridge, Charles Edward, University Institute.
*Flint, William Henry, Mason College.
*Foster, Henry Bertram, private study.
*Goodman, Harold, St. Bartholomew's Hospital and private tuition.
*Gowland, Edward Lake, University Tutorial College.
*Green, Sydney Balch, St. Bartholomew's Hospital.
*Harrison, John Wilkins, St. Paul's School and University Tutorial College.
*Hickinbotham, Edward B., King Edward High School, Birmingham, and private study.
*Hildesheim, Oscar, St. Paul's School.
*Hilton, Charles Guy Salter, private tuition.
Hunt, Sydney, Merchant Taylors' School.
*Judson, Joseph Edward, Owens College and private study.
Leah, Thomas, St. Mary's Hospital.
Marshall, Charles de Zouche, Eastbourne College.
Morgan, Daniel Leigh, Guy's Hospital.
*Morris, Frank Mayo, London Hospital.
*Moss, Bertram Wilmore, Guy's Hospital.
Orford, Thomas Christian, Owens College.
*Pancriddle, William Pancriddle, University and University Tutorial Colleges.
Payne, William, Carlyon College.
*Peck, William Edward, University Tutorial College and private study.
*Robson, Isabel, University College, Aberystwith, and private study.
Stallard, Nigel Frampton, University Tutorial College.
*Stark, Arthur Campbell, private study.
*Stevens, Andrew Norris, University Tutorial College.
Taylor, William Benjamin Batchelor, Merchant Taylors' School and London Hospital.
*Wells, Albert John Walton, St. Bartholomew's Hospital.
Whale, George Harold Lawson, private tuition.
*Williams, Sydney Rice, Merchant Venturers' Technical College, Bristol.
*Wigram, Charles Wynn, University College and private tuition.
*Wynne-Edwards, Edith Anna, University Tutorial College and private study.

BIOLOGY.

Addison, Oswald Lacy, University College.
Bourke, Isidore McWilliam, St. George's Hospital and private tuition.
*Bailey, William Herbert, Queen's College, Cambridge.
Bridger, James Frederick Edmund, St. Mary's Hospital and private study.
*Chetwood, Thomas, Epsom College.
Eisenberg, Herman Bernard, University College, Bristol.
*Foster, Arthur Herbert, Epsom College and St. Mary's Hospital.
Holland, Laurence, Mason College and private tuition.
*Jones, Lawrence, St. Paul's School.
*Judson, James Douglas, Owens College.
Klein, Joseph, University Tutorial College.
Lowe, Otto William Axel, private tuition and University College, Liverpool.
*Mennell, Zebulon, University Tutorial College and private tuition.
*Miller, Ernest Alfred, Guy's Hospital.
Miller, Thomas Davidson, University and University Tutorial Colleges and private tuition.
*Murrell, Christine Mary, University College.
*Noall, William Paynter, Owens College and private study.
*Nutt, Harold Rothery, St. Mary's Hospital.
*Ormond, Sidney James, Guy's Hospital.
*Paramore, Richard Horace, University Tutorial College.
*Pearce, John Warwick Guy, The Leys School and private tuition.
*Pock, Lawrence, University Tutorial College.
*Pocock, Arthur Robt. George, University College and private tuition.
*Ransford, Alan Carpmal, Dulwich College and Guy's Hospital.
*Robinson, Henry, St. Paul's School.
*Serase, James John Sheat, St. Bartholomew's Hospital.
Serjeant, Edith, Somerville Hall, Oxford.
*Stedman, Percy Taylor H., private study and tuition.
Stevens, Stanley, Carlyon College.
*Swift, Eric Wilson Danby, Firth College.
*Turnbull, Robert Cyril, Yorkshire College and London Hospital.
*Van Praagh, Harold John, St. Mary's Hospital.
Wallbridge, Stephen Edwin Joseph, St. Mary's Hospital.
*Watson, William Bertram, St. Mary's Hospital.
*Wolstenholme, Henry, University College and private tuition.
* These candidates have now completed the examination.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Weintraud of Strasburg has been recognised as *privat-docent* in Medicine.—*Kazan*: Dr. Fortunatoff has been promoted to the position of Ordinary Professor of Anatomy.—*Marburg*: Dr. von Büngner has been promoted to an Extraordinary Professorship of Surgery.—*Prague*: *Bohemian University*: Dr. V. Janovsky has been promoted to the position of Ordinary Professor of Dermatology and Syphilis. *German University*: Dr. Paul Dietrich has been promoted to the position of Ordinary Professor of Forensic Medicine.—*Tübingen*: Dr. Nagel has been recognised as *privat-docent* in Physiology.

PRESENTATION.—Dr. A. J. Helm Montague of Workshop has been presented with a case containing a pair of handsome electro-plated fish servers bearing the following inscription: "Presented to Dr. Montague by the St. John Ambulance class, Workshop, in recognition of his services as lecturer. February, 1895." At the same time Mrs. Montague received an electro-plated pickle fork from the same class.

THE Cambridge Medical Graduates' Club gave an informal smoking concert on Tuesday, Feb. 18th, at the St. James's Banqueting Hall, Regent-street, W. Each member of the club had the opportunity of introducing two friends, and the corresponding club, the Oxford Graduates' Medical Club, were invited as guests. There was no rigid programme, but most excellent music was kindly provided at intervals by Drs. Habershon, Shadwell, McCann, Fyffe, and Hayne, and Messrs. Burns, Gale and Marshall.

LITERARY INTELLIGENCE.—Messrs. J. & A. Churchill will publish next week a work entitled "The Insane and the Law; being a Plain Guide to Medical Men, Solicitors, and others," by Mr. G. Pitt-Lewis, Q.C., Recorder of Poole, Dr. Percy Smith, Medical Superintendent of Bethlem Hospital, and Mr. J. A. Hawke, B.A., late Scholar of St. John's College, Oxford. The same publishers have also nearly ready the second volume of "Chemical Technology," edited by Mr. C. E. Groves, F.R.S., and Mr. W. Thorp, B.Sc. This volume is devoted to Lighting by Candles and Oil, and is illustrated with nearly 350 figures. The section on Fats and Oils is contributed by Mr. W. I. Dent; Stearine, by Mr. John McArthur; Candle Manufacture, by Messrs. L. and M. A. Field; the Petroleum Industry, by Mr. Boverton Redwood; Lamps, by Mr. Redwood; and Miners' Safety Lamps, by Messrs. Redwood and D. A. Louis. The third volume of the same work, containing Gas Lighting, written by Mr. Charles Hunt of Birmingham; and Electric Lighting, by Professor Garnett, chairman of the Board of Technical Education, London County Council, is an advanced state.

FOOTBALL CASUALTY.—During a match at Bolton a player aged twenty-three years sustained "injuries to one of his legs." He was placed under medical treatment, but the injuries became more acute, and he died on the 15th inst.

ROYAL BRITISH NURSES' ASSOCIATION.—The third sessional lecture of the season was delivered at 17, Old Cavendish-street on Feb. 15th, before an appreciative audience, by Mr. W. Bezly Thorne, M.D., the subject being an Illustrated Explanation with Demonstration of the Physical Treatment of Heart Diseases. The chair was taken by Mr. J. Langton, F.R.C.S. At the conclusion the lecturer replied to the many intelligent questions raised on the various points of special interest to nurses.

A NEW WING of Weymouth Sanatorium was opened on Feb. 7th by Lady Ilchester, in presence of a large company. The Mayor, who presided, said that the sanatorium was founded in 1848 by the late Dr. Smith for the treatment of diseases of women and children. Originally there were six beds, but the applicants became so numerous that the committee acquired additional land and erected a detached wing containing three wards with accommodation for twelve patients.

THE OPIUM COMMISSION.—The report of this commission will be in the hands of Members of Parliament before Easter. The work of the commission has no doubt been unusually laborious and difficult, the evidence taken being very voluminous. The subject is one that gravely affects the habits and customs of the population of India for one thing, and the public finances of that country for another, consequently the publication of the results arrived at by the commission is anxiously awaited.

We learn from Bordeaux that a congress for the month of August next is being arranged for in that city under the auspices of the Société de Gynécologie d'Obstétrique et de Pédiatrie. The congress will be held upon the occasion of the thirteenth exhibition which the Philomathic Society of Bordeaux has organised. Professor Carnier will be the president of the whole congress, and the sectional presidents will be as follows: in Gynecology, Professor le Dentu; in Obstetrics, Professor Carnier; and in Pediatrics, Professor Lannelongue of Paris. The general secretary to the committee of organisation, to whom we owe the above information, is Professor Lefour.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 6th, Dr. Tew, President, being in the chair. Dr. Bell Taylor showed a man eighty years of age on whom he had successfully performed the operation of Cataract Extraction on the Left Eye without Iridectomy. He also showed: (1) three cases of Double Extraction; (2) a boy aged fifteen with Detachment of Retina, under treatment by galvanism; (3) a man aged forty-five who had been Blind for several months from disease of the Nerve, and whose sight had been restored by galvanism; and (4) a man aged forty-seven in whom Symblepharon of the Left Eye had been treated by a graft of skin transplanted from the right upper eyelid. Dr. Carroll showed a man aged forty-five who had been much benefited for Psoriasis by thyroid tabloids, four daily for nine months. Dr. William Ransom showed a woman aged thirty-four suffering from Acromegaly, associated with Glycosuria and Bi-temporal Hemianopia. Dr. Handford showed a man aged thirty-two with Splenic Leucocythæmia, who after the unsuccessful use of marrow tabloids and extract had improved greatly under arsenic. Mr. Anderson related three cases of Ligature of the Common Carotid Artery. In the first case the operation was done for aneurysm in the neck. Pulsation having returned, the sac was dissected out, and this was followed by death shortly afterwards. In the other two cases the carotid was ligatured in the course of the removal of malignant growths, and both cases recovered. Mr. Chicken showed the Vermiform Appendix removed post mortem from a male patient who had died from syncope occurring in the course of an acute abdominal illness. Two members of the same family had suffered from illness, in one case fatal, supposed to be due to disease of the same region. Specimens were exhibited: by Dr. Wm. Ransom, Actinomyces; by Dr. Handford, Leucocythæmic Blood; and by Mr. Anderson, Aneurysm of Common Carotid, and part of Prostate and Calculus removed by cystotomy.

The annual meeting of the East Grinstead Cottage Hospital was held on Feb. 12th at the Victoria Hall, East Grinstead, Mr. J. McAndrew presiding. During the year 1894 there were 43 patients under treatment; these included 28 surgical cases, of which 11 were of a serious nature. No death occurred during the year. The financial statement given in the committee's sixth annual report was satisfactory. A bequest of £45 was received from the executors of Mrs. Hort.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Infirmary for Waterford.

Mr. JOHN RILDON has introduced a Bill into the House of Commons for the establishment of a public infirmary in the city of Waterford. The Bill has been put down for second reading on Monday, March 4th.

Sanitary Registration Bill.

A Bill for the sanitary registration of dwelling-houses, schools, colleges, hospitals, asylums, workhouses, factories, workshops, hotels, lodging-houses, and other buildings within the United Kingdom has been introduced into the House of Lords by the Marquis of Ailesbury.

Burials Bill.

The Bill to amend the burial laws, introduced into the House of Commons by Mr. Caryell Williams, consists of nineteen clauses and a schedule. In the words of the memorandum, the main object of the measure is "to provide that while the consecration of parochial cemeteries may be permitted, consecration shall be regarded only as a religious rite, and shall create no legal rights or disabilities or claims to fees. The effect will be to give to burial authorities greater freedom than they now possess in regard to the laying out of cemeteries, the erection of mortuary chapels, &c." Clause 2 provides that where, after the commencement of the Act, any ground is appropriated as a public burial ground for a parish or district, the burial authority having jurisdiction over such burial ground shall sufficiently enclose and protect the same, but shall not permit any division to be made or other means to be taken of marking the boundaries of or distinguishing the consecrated and unconsecrated parts of such ground.

Certifying Surgeons under the Factory Acts.

The Departmental Committee of the Home Office on Factory Statistics have issued a long report in which they deal at considerable length with the examination by certifying surgeons of children and young persons. The committee find that in a certain number of instances annually the certifying surgeons fail to make any report and inasmuch as no remuneration is allowed for this part of their duty it is extremely difficult to secure compliance with the statutory obligation. In districts where young persons and children are rarely employed the return will necessarily be small, but the statistics cannot be regarded as complete unless a return, however limited the numbers concerned, be obtained from every certifying surgeon. To secure this end the committee say the question of remuneration ought to be considered. As to the medical reasons for rejection, these stated broadly, say the committee, are that the child is incompetent for the work in question or that owing to impaired health he would be likely to suffer ill consequences from the employment, or that his condition is such as to call for exclusion in the interest of his fellow workers. Some of the disqualifications which come under the first and second of these heads are relative only; that is to say, unsuitness for one particular kind of work does not of necessity mean unsuitness for all factory employment. Nor is it so regarded by certifying surgeons. It seems that in Lancashire deafness is held to be a ground of rejection, chiefly as regards employment in rooms where machinery is at work; but many children with imperfect hearing are passed on condition that they are employed in safe parts of the factory. Similarly the experience of some certifying surgeons has led them to regard carious teeth as a reason for rejection in lucifer match works. While regarding it as impracticable to institute any standard in such matters applicable to all industries in different parts of the country, the committee recommend that as a means to greater precision and uniformity, and also to more correct classification for the purpose of the annual report, a memorandum should be prepared with the assistance of some of the most experienced of the certifying surgeons embodying suggestions and instructions for the guidance of certifying surgeons generally.

BOOKS ETC. RECEIVED.

ALCAN, FÉLIX, Boulevard Saint-Germain, Paris.

Manuel de Percussion et d'Auscultation. Par le Dr. Paul Simon.

Sänger; February, 1895 (Williams & Norgate, Henrietta-street, Covent-garden, London).

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- ATKINSON, H. N. C.**, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Warneford Hospital, Leamington.
- BANKS, L. P.**, L.R.C.P. Irel., L.F.P.S. Glasg., has been reappointed Honorary Surgeon to the Mansfield and Mansfield Woodhouse District Hospital.
- BODINGTON, G. F.**, M.D. Durh. and Glessen, M.R.C.P. Lond., F.R.C.S., L.M. Eng., has been appointed Medical Superintendent to the New Westminster Asylum, British Columbia, Canada.
- BRIGGS, H.**, M.B., C.M. Edin., F.R.C.S. Eng., has been reappointed Honorary Surgeon to the Liverpool Hospital for Women.
- BURTON, J. E.**, L.R.C.P. Lond., M.R.C.S., L.F.P.S. Glasg., L.M., has been reappointed Honorary Surgeon to the Liverpool Hospital for Women.
- CHADWICK, C. M.**, M.D. Oxon., M.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician to the Victoria Home for Invalid Ladies, Leeds.
- COCHRANE, ROBT. S.**, M.B. Dub. Univ., F.R.C.S.I., has been appointed Medical Officer to the Longford Union.
- CREST, G. I.**, L.R.C.P., L.M., L.R.C.S. Irel., has been reappointed Honorary Surgeon to the Mansfield and Mansfield Woodhouse District Hospital.
- CURRIE, J. M.B.**, M.S. Edin., has been appointed House Surgeon to the Beckett Hospital and Dispensary, Barnsley.
- DAVIES, E. T.**, M.D., C.M., F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Surgeon to the Liverpool Hospital for Women.
- EDIS, J. B.**, L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Honorary Surgeon to the Liverpool Hospital for Women.
- GODFREY, G. P.**, L.R.C.P., L.R.C.S. Edin., has been reappointed Honorary Surgeon to the Mansfield and Mansfield Woodhouse District Hospital.
- GRINSDALE, T. B.**, M.B. Cantab., M.R.C.S., has been reappointed Honorary Assistant Surgeon to the Liverpool Hospital for Women.
- HARPER, W. J.**, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Sixth Sanitary District of the Barnstable Union.
- HARTLEY, R. N.**, M.B., B.S. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Victoria Home for Invalid Ladies, Leeds.
- JONES, E. L.**, M.D. Camb., B.S., has been appointed Pathologist to the Addenbrooke's Hospital, Cambridge.
- KAY, JOSEPH H.**, M.D., C.M. Edin., has been appointed Medical Officer for the Colne Sanitary District of the Burnley Union.
- KRITH, MRS. CAROLINE**, L.R.C.S., L.R.C.P. Edin., has been appointed Anaesthetist to the Chelsea Hospital for Women, Fulham-road.
- LANDER, H. W. G.**, M.B., C.M. Edin., has been appointed Assistant House Surgeon to the District Hospital, West Bromwich, vice O. H. Isard, resigned.
- MACGREGOR, G. S.**, M.B., C.M. Edin., has been appointed Examining Medical Officer to the Glasgow Convalescent Home.
- MACVICKER, C. G.**, M.B., B.S. Irel., has been appointed Medical Officer for the Eighth Sanitary District of the Newmarket Union.
- MILLS-ROBERTS, E. A.**, M.B., C.M. Edin., has been appointed Surgeon to the Penrhyn Quarry Hospital.
- PARKINSON, W. G.**, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Leeds Hospital for Women and Children.

PERRY, F. W., L.R.C.P., L.R.C.S., L.M. Irel., has been reappointed House Surgeon to the Pendleton Branch Dispensary, Salford Royal Hospital.

ROBINSON, F. G., M.B. Vict., L.R.C.P. Lond., M.R.C.S., has been reappointed District Medical Officer for the Broughton Branch, Salford Royal Hospital.

SMART, DAVID, M.B., C.M. Edin., has been reappointed Honorary Assistant Surgeon to the Liverpool Hospital for Women.

SMITH, H. W., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Mansfield and Mansfield Woodhouse District Hospital.

SMITH, W. B., L.R.C.P. Edin., M.R.C.S., has been reappointed District Medical Officer to the Salford Royal Hospital.

SPARKE, G. W., M.R.C.S., L.M., has been appointed Honorary Consulting Surgeon to the Mansfield and Mansfield Woodhouse District Hospital.

STEWART, MALCOLM, L.R.C.P. Edin., L.R.C.S. and L.M. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Parish of Eric and Rendall, Orkney.

STUCK, S. J., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Chelsea Hospital for Women, Fulham-road.

WORTS, E., L.R.C.P. Lond., M.R.C.S., has been reappointed Surgeon to the Essex and Colchester General Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

GURST HOSPITAL, Dudley.—Resident Assistant House Surgeon, for six months. Board, lodging, and washing in hospital provided.

HOSPITAL FOR WOMEN (the London School of Gynecology), Soho-square, W.—Clinical Assistants.

NORTH LONDON CONSUMPTION HOSPITAL, Hampstead, N.W.—Resident Medical Officer for one year. Honorarium £40 per annum, with board, rooms, &c., in the hospital. Applications to the Secretary. Offices: 41, Fitzroy-square, London, W.

NORTHUMBRIAN COUNTY LUNATIC ASYLUM, Morpeth.—Assistant Medical Officer, unmarried. Salary £120 per annum, increasing £10 yearly, to £150, with furnished apartments, board, and lodging.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London, N.W.—Resident Medical Officer for four months. Salary at the rate of £60 per annum, with board and residence.

ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY, Wigan.—Junior House Surgeon. Salary £80 a year, with apartments and rations (wines, spirits, and washing are not included).

ROYAL SURREY COUNTY HOSPITAL, Guildford.—Assistant House Surgeon. Board, residence, and laundry provided.

ROYAL INFIRMARY, HULL.—Senior House Surgeon, unmarried. Salary £100 per annum, with board and furnished apartments.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY, 60, King-street, Golden-square, W.—Resident Medical Officer. Salary £100, with furnished rooms, fuel, light, and attendance.

WORCESTER COUNTY AND CITY LUNATIC ASYLUM.—Third Assistant Medical Officer; unmarried. Salary commences at £100 per annum, with board, lodging, and washing. Applications to Dr. Cooke, The Asylum, Powick, near Worcester.

Births, Marriages, and Deaths.

BIRTHS.

PECK.—On Feb. 12th, at Ormskirk, the wife of Herbert Peck, L.R.C.P., L.R.C.S. Edin., of a daughter.

RAYNER.—On Feb. 18th, at 68, Porchester-terrace, W., the wife of Herbert E. Rayner, F.R.C.S., of a daughter (prematurely).

SELBY.—On Feb. 17th, at South-parade, Doncaster, the wife of E. W. Selby, M.B., B.S. Lond., F.R.C.S. Eng., of a daughter.

MARRIAGES.

DUKE—FITZROY.—On Jan. 26th, at the British Consulate General, Meshed, Persia, Surgeon-Captain A. L. Duke, I.M.S., to Frances Regina, daughter of the late Captain I. M. O. Fitzroy, R.A.

BLOOD—SCOTT.—On Feb. 18th, at St. Mary's, Chelmsford, Charles Reginald Elgood, M.D., B.S. Lond., of Windsor, to Edith Emma, only daughter of Charles Scott, of Chelmsford.

WALKER—HEYWOOD.—On Jan. 21st, at St. John's Church, Buenos Ayres, Henry Muirhead Walker, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of La Banda, youngest son of the late Dr. Arthur C. Walker, of Liverpool, to Lilian, youngest daughter of the late James Heywood, of Valparaiso, Chili.

DEATHS.

BLUETT.—On Feb. 18th, at his residence, Chesterfield, John Bluett, M.R.C.S., L.S.A., in his 80th year.

CHAMPNEYS.—On Feb. 11th, suddenly, at Hamilton House, Penge, Henry Montagu Champneys, F.R.C.S. Eng., in his 77th year.

HUBBERT.—On Feb. 16th, Philip Hubbert, M.H.C.S., L.S.A., of Meadow Bank, West Tarring, in his 81st year.

HULKE.—On Feb. 19th, at 10, Old Burlington-street, London, W., John Whitaker Hulke, F.R.S., President of the Royal College of Surgeons of England, aged 64.

TAYLOR.—On Jan. 11th, at Elmina, Gold Coast Colony, Wm. Taylor, M.D., Assistant Colonial Surgeon, late of the Jamaica Medical Service, aged 38.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (1 p.m.), St. Mark's (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynecological, by Physicians, 2 p.m.), Soho-square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), Guy's (1.30 p.m.), St. Thomas's (3.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1.30 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Gt. Northern Central (2.30 p.m.).

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing-cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (2.30 p.m.), Gt. Ormond-street (9.30 a.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing-cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (2 p.m.), Soho-square (2 p.m.), North West London (2 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Charing-cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Gt. Northern Central (2.30 p.m.).

SATURDAY.—Royal Free (9 a.m. and 2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), University College (9.15 a.m.), Charing-cross (3 p.m.), St. George's (1 p.m.), Cancer (2 p.m.).

At the Royal Eye Hospital (2 p.m.), the Royal London Ophthalmic (10 a.m.), the Royal Westminster Ophthalmic (1.30 p.m.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 p.m. Mr. J. D. Malcolm: Some cases of Liver and Gall Duct Surgery.—Dr. Wallis and Mr. E. Cotterell: A case of Craniectomy (the patient will be shown).

FRIDAY.—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Miller Hospital, Greenwich).—8.15 p.m. Clinical Evening. Card Specimens and Cases by Mr. John Poland, Dr. Herschell, Dr. Tayler, Mr. J. P. Purvis, Dr. Ezard, and Mr. Ernest Clarke.

CLINICAL SOCIETY OF LONDON.—8.30 p.m. Agenda as announced in THE LANCET of Feb. 16th.

ÆSCULAPIAN SOCIETY OF LONDON.—9 p.m. Adjourned discussion on "The Action of Cardiac Tonics." Mr. H. P. Miller: A case of Diphtheria: Antitoxin and Tracheotomy.—Dr. J. W. Hunt: Synopsis of 1000 cases of Midwifery.—Dr. G. Elam: A case of Facial Paralysis (living specimen).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 p.m., Mr. A. S. Morton: Affections of Eyelids.—London Throat Hospital, Gt. Portland-st., W., 8 p.m., Mr. G. Stoker: Post-nasal Growths and Enlarged Tonsils.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 p.m., Dr. Percy Smith: Puerperal and Lactational Insanity.

ROYAL BRITISH NURSES' ASSOCIATION.—8 p.m. Dr. W. S. Colman: Convulsions and the Training of Weak-minded Children.

WEDNESDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 p.m., Mr. A. S. Morton: Optic Neuritis.—Hospital for Skin Diseases, Blackfriars, 1 p.m., Dr. Payne: Eczema, its Varieties.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 p.m. Lecture by Dr. Gowers.

WEST LONDON HOSPITAL (Hammersmith-rd., W.).—5 p.m. Dr. W. Hunter: Pernicious Anæmia. (Post-graduate Lecture.)

HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 p.m. Lecture by Prof. Clifford Allbutt on "Senile Plethora (High Arterial Tension in the Aged)."

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 p.m., Mr. Donald Gunn: Ophthalmia.—National Hospital for the Paralyzed, Bloomsbury, 2 p.m., Dr. Baastian: Cases in the Hospital.—Central London Sick Asylum, Cleveland-st., W., 5.30 p.m., Mr. Bryant: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 p.m., Prof. Crookshank: Tuberculosis and Leprosy.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 p.m. Mr. F. Bowreman Jessett: Cancer of the Uterus.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 a.m., Dr. Hyslop: Developmental Insanity; Circular Insanity.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

COUNTY COURTS AND MEDICAL CERTIFICATES.

THE medical profession will accept gratefully any reasonable suggestion from the authorities on the question of medical certificates. We notice one by Mr. Registrar Stone in the County-court, Tunbridge Wells. A defendant excused his non-attendance on a medical certificate. The Registrar demurred on the ground of the vagueness of the certificate—which only stated that the person "must not venture out"—and stated that reasons must be given for the non-attendance. Time was given for the defendant that he might obtain a more definite certificate. There is some reason in this, and medical men will do well to take notice and make their certificates more specific. It is conceivable that there are cases in which too much definition would be inconvenient and unjust; but the medical man must put his ingenuity to the test of meeting reasonable demands and yet not betraying professional confidence.

Mr. R. W. Carshall.—The question is a new one. We do not see that our correspondent need be deterred from conducting the business that he mentions, and therefore from duly advertising it in the medical press. We take it for granted that our correspondent intends to remain aloof from practice; for it would not be right to carry on both vocations.

Asterion has omitted to enclose his name and address.

APPOINTMENT OF PRISON SURGEONS.

To the Editors of THE LANCET.

SIRS,—Can you inform me where to apply for an appointment as colonial surgeon or surgeon to one of Her Majesty's Prisons? Is a married man eligible for either appointment?

I am, Sirs, yours faithfully,

Scarborough, Feb. 19th, 1895. H. Y. WALKER, M.R.C.S., L.R.C.P.

* Application for the appointment of prison surgeon should be made to the Prison Commissioners at the Home Office, Whitehall, S.W. (Secretary: Col. M. Clare Garsia), for English appointments, and the candidates are selected on their merits. Medical officers in Scotch and Irish prisons are appointed by the same department, but under separate regulations. The Secretary of State for the Colonies appoints the colonial surgeons and the surgeons and assistant surgeons to the convict prisons abroad. We believe that a married man is eligible for all these appointments; but no doubt the secretaries of the different Government bodies would answer all inquiries.—**ED. L.**

MEDICAL ADVERTISING IN THE UNITED STATES.

A CORRESPONDENT with British qualifications but long resident in the United States is much concerned at the methods of publicity used by even leading medical men in the States. The proceedings of medical societies are reported in the newspapers. A hysterectomy will be detailed for the gratification of their readers under the head of "A Most Delicate Surgical Operation," at which Dr. So-and-So exceeded himself, and was assisted by Dr. — of the Hospital &c., &c.; the operation lasted three hours and fifteen minutes. "So important and delicate was the operation that twenty-three doctors, not including those above mentioned, were present." This stroke reminds us of that touch of Addisonian humour in Sir James Paget's narrative of an illness of his own in our columns—that he had had eleven medical attendants, and that his was the only case he knew of recovery where so many had been consulted. The business columns will contain advertisements of Dr. —'s blood tonics, antiseptic solutions, &c. Another will tell the public that he will henceforth dispense his own medicines and have for sale a number of remedies prepared from favourite prescriptions of his, &c. The said Dr. — is a member of the local medical societies, and was formerly president of the Medical Society. Our correspondent thinks that these methods, so far from dying out, are on the increase. We regret to hear it. We are not without beams in our own eye; but it would be a new sight in English newspapers to see our medical societies' proceedings reported or hysterectomies described. We cannot doubt that our brethren in the States will come to see that such methods are best left to men without standing and without qualifications.

Nit Desperandum.—It is not usual to charge for death certificates supplied to the registrar, in accordance with the Registration Act.

"DEATHS UNDER ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—May I venture to emphasise the comments you made on the death under chloroform which occurred at the Bristol Infirmary, reported in THE LANCET of Feb. 2nd. From personal experience of a considerable number of hospital cases I have come to the conclusion that by suddenly or violently moving a patient incompletely under the influence of an anæsthetic a very marked inhibitory influence to the cardiac centre is initiated. I have repeatedly noticed that immediately after lifting a patient on to or off the operation table, which is frequently done just before or just after total anæsthesia, there has been a marked fall in the pulse tension, with slowing of the respiration, these dangerous symptoms being absent if the patient is fully "under" whilst being moved. I have frequently observed the respiration become extremely shallow and the pulse fluttering during the manipulations necessary to apply a bandage to the abdomen or chest, the administration of the anæsthetic having been stopped some minutes before this was done. I should also like to bear testimony to the value of nitrite of amyl in cases of threatened cardiac failure during chloroform administration. The inhalation of three or four minims of this drug, together with the application of large hot sponges over the cardiac region, has acted as a most valuable circulatory stimulant.

I am, Sirs, yours truly,

Feb. 4th, 1895. J. H. MARSH, M.R.C.S., L.R.C.P. Lond.,
Senior House Surgeon, the Infirmary, Macclesfield.

"SAVE ME FROM MY FRIENDS."

OUR attention has been directed to the following editorial paragraph from the *Glasgow Evening News*:—

"Dr. John McIntyre, the well-known Bath-street specialist in throat surgery, was in the middle of an interesting limelight lecture to the Society of Musicians in the Philosophical Society's Hall on Monday night, when he was summoned to Hillhead to perform the operation of tracheotomy on a child in *extremis* from diphtheria. Permission to break off the lecture was cheerfully given by the audience. The doctor bolted, and within an hour was back at his residence, having performed the operation with success, and got the child out of immediate danger."

The paragraph is doubtless the work of some zealous, but very injudicious, friend, and will be deprecated and resented by Dr. McIntyre not less than by our correspondents and ourselves.

Mr. Alf. Back.—We do not act as assessors on medical treatment or diagnosis, and we do not give medical advice. We recommend our correspondent to consult his medical man as to the suitability of the treatment to which he alludes.

"SUCCOUS ALTERANS."

To the Editors of THE LANCET.

SIRS,—I should be thankful if any of your numerous readers could give their experience of a new drug called "succus alterans," an American preparation, I believe, which is recommended in tertiary syphilis, eczema, &c. I am anxious to know if there be any evidence of its efficacy in the later stages of syphilis.

Feb. 18th, 1895. I am, Sirs, yours faithfully,
CRUICK.

"WANTED, HISTOLOGICAL SLIDES."

WE have received from numerous correspondents the names and addresses of persons who supply histological slides. We recommend "Member" to apply to the leading opticians. A few surgical instrument manufacturers and a few chemists and druggists also keep histological slides in stock.

"A CASE OF DIPHTHERIA SUCCESSFULLY TREATED BY INSUFFLATIONS AND TABLOIDS OF PURE SULPHITE OF MAGNESIUM."

To the Editors of THE LANCET.

SIRS,—Dr. Brownlow Martin's article under the above heading in your issue of Feb. 9th reminds me of some interesting experiences I have had with this valuable drug since my letter to THE LANCET of Aug. 25th, 1894, on this subject. On Oct. 11th I saw a child suffering from sore-throat, who, the mother informed me, had been the previous week playing with two other children who had been attacked with diphtheria and subsequently succumbed to the disease. On examination I found a small greyish patch on the right tonsil. I prescribed tabloids of sulphite of magnesium, chiefly because the child had possibly been exposed to contagion, and the appearance of the throat, though not at all alarming, was somewhat suspicious. Next day the child was quite well. As the attack was slight and its nature doubtful, I sent no notification to the medical officer of health. On Oct. 15th I was again called to see two other children in the same house—an elder brother and sister of the first patient. There could be no doubt this time. Both children were suffering from diphtheria. The membrane was abundant enough to satisfy the most sceptic diagnostician. Four days after (on the 20th) the mother, who was *enclave*, contracted the disease in a rather aggravated form. The throat was enormously swollen; the membrane covered the fauces; there were high fever, marked prostration, and albuminuria, as well as symptoms of threatened miscarriage. All these cases were treated with insufflations and tabloids of sulphite of magnesium. All recovered. On the 27th of the same month a boy aged seven, living next door to these patients, had an attack of diphtheria. The disease at first yielded quickly to treatment, but the membrane rapidly reappeared in the pharynx, with hard, dry cough, hoarseness, and dyspnoea, showing that the larynx was attacked. The boy was very obstinate at first, and there was a good deal of difficulty in using the insufflator. He recovered after a hard struggle, and I am quite satisfied that with any other treatment I ever saw tried the result would not have been quite as satisfactory. Let me hasten to say that I have not tried antitoxin. For some time I have decided to do so on the first occasion that the sulphite was unsuccessful. The results I have had from this treatment have been so excellent that the occasion has not yet arisen. Even in the absence of bacteriological evidence there can be no reasonable doubt about the correctness of the diagnosis in these five cases. Besides these, I have, since I wrote to THE LANCET in August last (excluding some more or less doubtful cases) attended three others in which the disease was sufficiently marked to justify one in claiming to be clinically certain. In one of these there was slight albuminuria, as well as the characteristic membrane. In another the diagnosis was strengthened by a second medical opinion. In each of these cases the sulphite was used. The membrane quickly disappeared, and in each instance the attack was mild. If the results from sulphur be as satisfactory as those obtained from the use of sulphite of magnesium I can easily understand the enthusiasm of its advocates in recent issues of THE LANCET. If the treatment suggested by Dr. Brownlow Martin got as extensive a trial as that of M. Roux the death-rate from diphtheria might possibly be still further reduced.

I am, Sirs, yours faithfully,

W. G. NIALL.

Guildford, Feb. 10th, 1895.

THE EXPLOITS OF A BONESETTER.

To the Editors of THE LANCET.

SIRS,—I enclose two cuttings from the local press, which may be of interest to you. They recite the glorious achievements of the local bonesetter, who has been sufficiently fortunate to meet with three dislocations of the knee and one of the clavicle out of a total of fifteen cases of injury. You probably have no idea of the extent to which this sort of thing goes on here. We are constantly having it thrust before our eyes in glaring form. My object in writing is to get an expression of opinion from yourselves and also from members of the medical profession upon the following points. 1. What should be our attitude when requested to see a patient who is under the treatment of an unqualified bonesetter—whether to look after every other part of the patient's body except the bones, or simply to sign the club certificate and, if necessary, the death certificate? 2. Can nothing be done to compel these men to qualify? 3. Does it amount to "covering" if a medical man lends his presence, and perhaps his skill, in a case where the chief injury is being wholly treated by an absolutely unqualified man?

I am, Sirs, yours faithfully,

FAIR PLAY.

Feb. 5th, 1895.

"QUALIFIED DISPENSERS."

To the Editors of THE LANCET.

SIRS,—By the Apothecaries' Hall qualification is meant the certificate of qualification issued by the Apothecaries' Society to act as an assistant to an apothecary in compounding and dispensing medicines.

I am, Sirs, yours faithfully,

COLLOID.

Feb. 18th, 1895.

AMERICAN QUACKERY IN JOHANNESBURG, TRANSVAAL.

ONE of the most prodigious of the American advertisers in Johannesburg is Dr. Johnson—a specialist in all diseases that can be mentioned. The newspaper advertisements include the cure of gonorrhoea with two or three applications. Can the State University Medical College of Colorado, U.S., bring any influence to bear on such a public scandal? Another offender against professional morals is Dr. Strong of Johannesburg, who says his United States diplomas have been examined by the Board of Medical Examiners of the South African Republic, from whom he has received a licence to practise. Has this Board no control over its licensees? It is high time that some such control was shown to exist.

"SULPHUR P. ANTITOXIN IN THE TREATMENT OF DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—Dr. Hamilton, in THE LANCET of Feb. 2nd, replies to a letter of mine of the 26th ult., and states that he has used sulphur dusting for years in diphtheria, and still uses it in conjunction with antitoxin. As he still uses sulphur partially it must be difficult to say how far his good results are due to the one or the other of the remedies used. As long as the profession will persist in treating cases at one and the same time with two or more remedies it is impossible to say how far each individual remedy is responsible for the result obtained. That Dr. Hamilton's case of diphtheria began to improve after injecting antitoxin twenty-four hours previously really proves nothing, for many cases improve after four days' treatment without using either antitoxin or sulphur, or, indeed, any other drug. Sulphur, like every other remedy, must have time to act. The days of miracles have gone by. From my own personal inquiries and from consulting various authors, including Taylor, Fagge, and Lennox Browne, and finding no reference in Neale's Medical Digest, 1882, I have come to the conclusion that a very small proportion of the profession have given sulphur a fair trial. I am carefully watching the results of treatment by antitoxin, and as yet have seen none that are so good as those of others and my own who have given sulphur a fair trial. The bridge sulphur has carried me over so far without a fatality—a coincidence possibly. At the same time I think I should be deserving of a stronger name than "faddist" if I blindly deserted an old and tried friend which is harmless for an untried stranger which may or may not be harmless. I ask Dr. Hamilton to use sulphur both internally and locally in a given number of cases and antitoxin without sulphur in an equal number, and contrast the two results. I am certainly not a faddist, and am open to conviction when results justify that conviction.

I am, Sirs, yours faithfully,

Aberdovey, N. Wales, Feb. 11th, 1895.

W. HAWKINS CUTBERT.

"TREATMENT OF TAPEWORM."

To the Editors of THE LANCET.

SIRS,—Many years ago I was giving a patient a mixture as follows: Hydriodate of potash, gr. xxxvi.; iodine, gr. xii.; water, ʒi.—ten drops three times a day in water. The patient unexpectedly passed a tapeworm eleven yards long, dead, of which there were no previous symptoms. I have since given the same medicine successfully in two or three cases. The last patient came to me about three years since and stated that he had suffered from tapeworm for two years and was constantly passing tapeworm, but it always returned. I gave him the same medicine, and after a short time he passed a mass of tapeworm dead, and there has been no return. Perhaps "A.M.S." will give the result if he tries the same remedy.

I am, Sirs, yours obediently,

Tenterden, Feb. 5th, 1895.

JESSE H. NEWINGTON.

"THE EXHIBITION OF HYPNOTISED SUBJECTS."

To the Editors of THE LANCET.

SIRS,—In reference to the case of trance now exhibiting at the Royal Aquarium, Westminster, will you kindly allow me to call the attention of your readers to my papers on the relation of the sympathetic nerve to disorders of sensation and mentation? The first paper was published in THE LANCET of Sept. 26th, 1868, and other papers in the Medical Times and Gazette of Oct. 28th, 1871, and Dec. 16th, 1871, and Aug. 31st, 1872. I venture to think that this aspect of the pathology of sentience will throw some light on the subject.

I am, Sirs, yours faithfully,

Lancaster, Feb. 14th, 1895.

METCALFE JOHNSON.

During the week marked copies of the following newspapers have been received:—Birmingham Post, Torquay Times, Kent Herald, Brighton Gazette, Darwen Post, South Austell Star, Hereford Journal, Cambridgeshire Times, Scotsman, Bristol Times, Walsall Advertiser, Sussex Daily News, Truth, Evesham Journal, Le Temps (Paris), North Star, New York Herald, Rochdale Observer, Yorkshire Herald, Glasgow Evening News, Public Opinion, Dublin Evening Telegraph, Wigan Examiner, Manchester Courier, Huddersfield Examiner, Science Signings, Leeds Mercury, Horncastle News, City Press, Yorkshire Post, Isle of Man Times, Craven Herald, St. Bartholomew's Hospital Journal, Reading Mercury, Surrey Advertiser, Alliance News, North Devon Herald, Cumberland Packet, Waterford Mirror, Spalding Free Press, Huddersfield Chronicle, Hellenburgh Times, West Middlesex Advertiser, Lincolnshire Echo, Isle of Wight Mercury, Cornish Telegraph, Lynn News, Devizes Gazette, Kington News, Tottenham and Stamford Hill Times, &c., &c.

Communications, Letters &c. have been received from—

- A.**—Messrs. P. Alcan, Paris; Messrs. C. Ash and Sons, Lond.; Messrs. Allen and Hambury, Lond.; Messrs. Agar Bros., Manchester; A General Practitioner.
- B.**—Dr. P. Boohyer, Nottingham; Dr. Bateman, Lingfield; Dr. D. C. Black, Glasgow; Mr. L. A. Bidwell, Lond.; Mr. J. F. Bullar, Southampton; Mr. C. A. G. Browne, Lond.; Mr. W. H. Best, Ilford; Mr. J. A. Bartlett, Lond.; Mrs. E. J. Bellaser, Bath; Miss Baker, Reigate; Messrs. Blackie and Son, Lond.; Messrs. Brady and Martin, Newcastle-on-Tyne; Messrs. Burgoyne, Burdighes and Co., Lond.; Brit. Med. Assoc., Lond.; Librarian of; Biltor Co., Lond.; Baynam.
- C.**—Dr. E. K. Campbell, Lond.; Mr. R. C. Coward, Lond.; Mr. W. P. Clay, Edinburgh; Mr. A. J. H. Crespi, Wimborne; Mr. F. W. Chapman, Chester; Mr. R. A. Caldwell, Southampton; Rev. W. Conway, Connemara; Mr. Clark, Wolverhampton; Messrs. Catton and Puckey, Lond.; Messrs. J. and A. Churchill, Lond.; Messrs. T. and A. Constable, Edinburgh; C. T. W., Lond.
- D.**—Dr. C. J. Da Cunha, Daum, Portuguese India; Dr. Dale, Nottingham; Mr. F. Davis, Lond.; Mr. J. W. Davies, Elbow Vale; Mr. H. W. Deunely, Horsham; Dewsbury Gen. Infy., Sec. of.
- E.**—Mr. E. W. A. Elliott, Lond.; Rev. R. A. Edgell, Leamington; Messrs. Evans, Lescher and Webb, Lond.; Enquirer; Knquiry.
- F.**—Mr. L. A. Freeth, Woolston.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded. Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Three Lectures

ON

TRAUMATIC INFECTION,

Delivered at the Royal College of Surgeons of England on
Feb. 25th and 27th, and March 1st, 1895.

By C. B. LOCKWOOD, F.R.C.S. ENG.,

PROFESSOR IN SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS;
ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; SURGEON
TO THE GREAT NORTHERN CENTRAL HOSPITAL.

LECTURE I.

Delivered Feb. 25th.

SOME LOCAL INFECTIONS.

Methods of Investigation.—*Cadaveric Bacteria a Source of Error.*—*Classification of Material.*—*Mycotic Peritonitis.*—*Diffuse Septic Peritonitis.*—*Lymphatic Glands in Diffuse Septic Peritonitis.*—*Operative Peritonitis.*—*Perforative Peritonitis.*—*Streptococcus Peritonitis.*—*Streptococcus Pleuritis.*—*Bacterial Invasion of the Peritoneal Lymph Paths in Septic Peritonitis.*—*Intestinal Bacteria in other conditions; in Hepatic Abscess; in Typhoid Abscess.*

GENTLEMEN,—For some years, with the help of friends and pupils, to whom I am deeply indebted, I have worked at various kinds of traumatic infection. The results are given in these lectures. It will be obvious, and I am fully conscious, that in many instances the inquiries are incomplete; nevertheless, I venture to hope that light is thrown upon some conditions, and that what has been done may be helpful to my fellow workers. Throughout these lectures the gaps which ought to have been filled are pointed out, and no attempt has been made to give an appearance of completeness.

METHODS OF INVESTIGATION.

My plan has been to choose cases of traumatic infection of which the clinical history and morbid anatomy were known and work out their morbid histology. Nearly all the cases were under my observation when surgical registrar in St. Bartholomew's Hospital, and of many of them I conducted the post-mortem examination. This order has not always been strictly adhered to, but, as an extra control, the clinical history and morbid anatomy were often purposely left unascertained until the morbid histology and bacteriology had been investigated. Although it may be rather tedious and prolix, I propose to illustrate each branch of my subject with these cases, giving the clinical history, morbid anatomy, morbid histology, and as far as possible the bacteriology of each. I venture to surmise that it must be advantageous to an audience of surgeons to be able to consider all of these together and in continuity. A short commentary follows each case, and in this some of the more recent researches bearing upon it are mentioned. I need not speak about the clinical and anatomical methods. For histological purposes the tissues were obtained as fresh as possible and hardened in alcohol. The sections were stained in various ways. Sometimes good results were obtained by Gram's method, but nearly all the best were got by using, upon Dr. Klein's advice, a staining solution which was used by Canon to demonstrate the influenza bacillus in blood, and which is called Czenzynke's solution.¹ This is a mixture made by adding together a concentrated watery solution of methyl blue 40 per cent.,² eosin solution (in 70 per cent. of alcohol), 20 per cent., and distilled water 40 per cent. The sections of the hardened tissues were soaked in the above solution for not less than seventy-two hours, and often for seven or eight days. The sections were mounted in the usual way. As the bacteria are stained blue and the tissues pink, their presence is easily ascertained; but we have found the pink ground most unsuitable for micro-photography. However, Czenzynke's solution has stained bacteria when nearly all of the ordinary methods have failed. Nevertheless, it has one great demerit. Many of the specimens fade and lose their brilliancy after a few months, so that it is necessary

to draw them at once. Micro-photography would be especially useful under these circumstances, but, unfortunately, it cannot be used for the reasons given. I have, therefore, been obliged to make drawings of the most instructive of the sections. These, together with the specimens themselves, are displayed for your inspection. The drawings have been made into lantern-slides by my friend, Mr. Cosens, to whom I am deeply indebted for invaluable assistance. My experience of Czenzynke's method shows that it should be used with caution. The protoplasm of the connective tissue cells often holds particles of the aniline blue, so as to simulate bacteria. However, the irregular shape and size of the particles, the absence of that peculiar translucent hue which dyed bacteria possess, and the presence of a nucleus, is enough to prevent an error. No material was discarded until all kinds of methods had been tried upon it. Many months were often devoted to these endeavours. The ultimate result was often highly satisfactory.

CADAVERIC BACTERIA A SOURCE OF ERROR.

In work like this there is great danger of mistaking bacteria which have grown in the tissues after death for those which may have existed during life. In hot weather these cadaveric bacteria grow very quickly, and material can seldom be obtained for histological examination until some hours after death. However, I trust it will be acknowledged that this source of error has been guarded against throughout these lectures. In doubtful cases the question is discussed in the commentary, and some material has been put aside because the tissue changes and bacteria were probably of post-mortem origin. An important rôle has not been ascribed to bacteria unless they were present in numbers and amidst tissue changes such as could only have occurred during life, and such as might reasonably be ascribed to their presence. The bacteria of putrefaction are distinguished by morphological peculiarities, by the situations in which they grow, and by the absence of pathological changes in their vicinity. But much work remains to be done at the cadaveric bacteria, and even with the greatest caution they remain an abiding source of error.

CLASSIFICATION OF MATERIAL.

The various cases which have been investigated fall naturally into the following groups. First, those in which the infection was local; second, those in which the infection had entered the blood, but had not passed any further; third, those in which the infection of the blood had passed into the tissues, producing changes there; and, lastly, some mixed infections. This classification of the cases is suggested more by convenience than scientific accuracy. Reasons will be given to show that even in the typical local infections there may have been some passage of bacteria through the blood to the kidneys, and perhaps to other organs.

MYCOTIC PERITONITIS.

I propose to begin the local infective diseases with acute inflammations of some of the serous sacs, commencing with septic peritonitis. And, first, a case will be given to show how easily peritonitis may be overlooked, and how bacterial invasion of the peritoneum may be unsuspected. In the following case I believe that an infection of the peritoneum had occurred, although during life no signs of it were recognised, and after death none were apparent to the naked eye.

CASE 1.—The case was that of a woman aged sixty-nine years, who had had a multilocular ovarian cyst removed. The peritoneum was drained for forty-eight hours after the operation because blood oozed from some slight adhesions. She did well until the fifth day, but then her temperature, which had hitherto been normal, rose to 101° F., and remained about that height until the tenth day, when she died. During life the abdomen seemed free from inflammation, and the fatal issue was attributed to bronchitis. At the examination, which I made twenty hours and a half after death, the wound was almost healed, and I expressly noted that no inflammation, fluid, or lymph could be seen in the peritoneal cavity, but merely slight localised hyperæmias. Around the pedicle of the right ovary, which was secured with silk, I especially noted that there was hardly any inflammation or lymph. All the abdominal viscera were healthy except the kidneys, which were chronically inflamed. The left pleural sac contained three quarters of a pint of purulent fluid, and the parietal and visceral pleura were covered with flakes of lymph. The lower lobe of the left lung was pneumonic and sank in water. The stump of the ovarian pedicle was examined histologically. There was

¹ Centralblatt für Bakteriologie und Parasitenkunde, Band xi., 1892, p. 149.

² I am accustomed to add 5 per cent. of carbolic acid to the watery solution. It keeps longer and acts quite as well, if not better.
No. 3731.

slight hyperæmia and here and there on the surface small masses of lymph, composed of exudative cells and bacteria. Amongst the latter were long bacilli with rounded ends and usually in pairs, and almost as big as anthrax bacilli; also short ovoid and very thick bacilli, together with vast quantities of smaller bacteria which grew singly, in pairs, and short strings. There may have been micrococci, but so many were slightly elongated that it is possible that all of them were minute oval bacilli. (Fig. 1.) Many of the smallest bacteria had entered the lymph paths and had filled both those near

FIG. 1.

Mycotic peritonitis. Lymph upon ovarian pedicle. The bacteria are upon the surface and in the lymph paths.

the surface and many of those in the depths of the peritoneum. (Fig. 2.) Here they surrounded a nuclear cell, which suggested that they had either been carried into the lymph paths by a wandering leucocyte or had surrounded one after their entrance. If these bacteria-laden cells were phagocytes they must have been singularly inefficient. Some would say that the bacteria which were found in this case were mere saprophytes which had travelled from the intestines after death. But if this were so it seems strange that they should only be found in the lymph and in the

FIG. 2.

Mycotic peritonitis. Bacteria in lymph spaces in tissues of ovarian pedicle.

lymph paths leading from it. The uninfamed parts of the peritoneum had no bacteria either upon its surface or in its depths. The silk upon the pedicle contained no bacteria, and none could be seen in the lymph in its immediate vicinity. I should suppose that the chemicals in which the silk had been soaked may have preserved it from infection. If this be so it would help to explain those cases in which silk is not extruded from wounds which are obviously septic. Until the histological examination I had no suspicion that such numbers of bacteria would be found in the peritoneum.

The question arises as to the share they had in the fatal ending. They hardly seem to have compassed this by acting locally upon the peritoneum. During life the clinical signs of peritonitis were wanting. However, I have no doubt but that they were the cause of the pleuro-pneumonia, which will presently be described.

Pawlowsky³ has made an important observation which bears upon such cases as this. He describes a variety of acute peritonitis which he calls mycotic peritonitis, in which there are no macroscopic appearances, but in which microbes can easily be obtained by pressing cover glasses upon the peritoneum and afterwards drying and staining them in the usual way. But this form of peritonitis is very acute; and death occurs very early and before fibrinous effusion or pus have had time to occur; life is not prolonged as in the instance which has just been given.

The histological examination of the lungs showed catarrhal pneumonia and pleuritis, with more corpuscles than fibrin in the exudation. The methods of Gram and Loeffler give negative results. But after we had all failed Mr. Soff obtained for me beautiful specimens showing that the pleuritic lymph was crowded with bacilli. Many of these were the shape and size of tubercle bacilli; some were slightly curved and some might have contained spores. They were distributed indiscriminately in the lymph, but some grew in short leptothrix. The lymph also contained vast numbers of small, short, ovoid bacilli. Both of these varieties may have belonged to the same species, and were the same as some of those seen in the peritoneal lymph. I was uncertain of the presence of these bacilli in the pneumonic lung. It probably contained pneumococci. Pleuritic exudation is not very hard to examine. In three other cases I have found in it streptococci (Fig. 8), pneumococci, and septicæmic bacilli respectively. With pneumonic lung I have been most unsuccessful, and when pneumococci have been seen they have been in such small numbers as to excite doubts as to their being the cause of the pneumonia. Acute inflammations of the lungs are associated with various bacteria. In the 128 cases examined by Weichselbaum⁴ the diplococcus pneumoniae was found in 94; a streptococcus in 21; staphylococcus pyogenes aureus and albus in 5 cases of pneumonia secondary to typhoid fever and osteomyelitis; and a bacillus pneumoniae, similar to Friedlander's pneumococcus, in 15 cases. In 11 cases of pleuritis a chain coccus was found. In conclusion, this case suggests that surgeons ought to be very cautious in assuming the absence of peritoneal infection. Also, that much might be learnt by a more rigorous and scientific examination of fatal cases. Towards the end of these lectures I will instance other cases to show the fallacy of a mere naked eye examination of the tissues.

DIFFUSE SEPTIC PERITONITIS.

During the past year I have been so fortunate as to cure by operation three cases of diffuse septic peritonitis. When we consider the clinical history and morbid anatomy of these cases such a result could hardly be hoped for. I have therefore tried to ascertain what light morbid anatomy and bacteriology threw upon the possibilities of recovery. The material which was used had all been collected long before the successful results occurred.

CASE 2 (Fig. 3).—To illustrate the rapidly fatal form of acute septic peritonitis I will give the case of a boy aged eight years, who was operated upon for the cure of a right inguinal hernia which he had had since his birth. At the time of operation there was an old septic sinus leading into the inguinal canal. This sinus was the result of a previous attempt to perform the radical cure. It led towards a ligature which, as afterwards appeared, had been placed upon the stump of a Meckel's diverticulum. It is unnecessary to give the details of the operation, but it will suffice to say that the boy died forty-eight hours after, with the usual signs of diffuse septic peritonitis. The highest temperature recorded was 102° F. At the examination the abdomen was distended, the viscera inflamed and coated with viscid lymph, and the pelvis and flanks nearly filled with purulent fluid. The chief focus of inflammation was around the right internal abdominal ring. No faecal matter could be found in the abdominal cavity. Twenty inches from the cæcum a Meckel's diverticulum grew from the ileum. It had been divided and encircled by silk

³ Centralblatt für Chirurgie, 1887, pp. 886 and 887.

⁴ Ueber die Aetiologie der acuten Lungen- und Rippenfellentzündungen. Wiener Medicinisches Jahrbuch, 1886, p. 433 et seq.

ligatures, which still fastened it to the abdominal wall. The sinus, which has been mentioned, ran towards these ligatures and opened into the abdominal cavity. It was evidently the centre of the septic peritonitis. The other end of the diverticulum was attached to the top of the right testicle. The microscope showed that all the peritoneal vessels were distended with blood, in which no bacteria could be found. In some places the blood cells were extravasated amongst the tissues, but otherwise the substance of the peritoneum had undergone hardly any alteration. Its surface, however, was covered with a thin layer of lymph, which was here and there crowded with swarms of small, short bacilli, growing in pairs and short chains. (Fig. 3.) The bacilli were confined to the surface lymph except in one

FIG. 3.

Diffuse septic peritonitis. Bacteria in the lymph upon the surface of the peritoneum and just within its substance.

place, where a single group lay about a hundredth part of an inch within the substance of the peritoneum. (Fig. 3.) Elsewhere the lymph paths contained neither pus cells nor bacteria. The inflammatory lymph consisted of cells with some fibrin. It is not certain, but probable, that these bacteria were intestinal in origin, and very likely the bacillus coli communis. The slightness of their penetration into the peritoneum may be explained by the very feeble mobility which the bacillus coli communis possesses, or by assuming that the swarms in which it grows are ill adapted to penetrate the tissues or to pass along the lymph paths. Therefore, in some kinds of diffuse septic peritonitis the peritoneum itself is not penetrated by the bacteria for many hours and its tissues are almost uninjured. Apparently, so far as the serous membrane itself is concerned, there is nothing to forbid recovery. Indeed, there is a close similarity betwixt the case which has just been described and one of my cases of diffuse septic peritonitis which did recover after laparotomy.⁶ In my case the peritonitis was of not less than forty-eight hours' duration, and was caused by a perforation of the ileum, which I found and sutured. At the operation the intestines were emptied of their fecal and gaseous contents and the peritoneal sac thoroughly washed out and drained. Whilst operating I observed that the mesenteric lymphatic glands were swollen to at least thrice their natural size. I did not then know what evil effects these inflamed glands might exercise. Fortunately, they seemed to depart without disturbance.

THE LYMPHATIC GLANDS IN DIFFUSE SEPTIC PERITONITIS.

Being inquisitive to know the characters of the lymphatic glands in diffuse septic peritonitis, I examined them in another case due to ulceration of the vermiform appendix.

CASE 3.—The patient was a boy aged seven years, whose illness began suddenly with a violent pain in the right side of the abdomen. This was soon followed by distension, inflammatory obstruction, and fecal vomiting. The abdomen was opened on the third day, and an inflamed and perforated vermiform appendix was removed. The peritoneal cavity was washed out and drained, but he died in four hours.

I obtained portions of the peritoneum and some of the swollen lymphatic glands within eighteen hours of his death. The appearances of the peritoneum were almost the same as in the previous case (Case 2, Fig. 3). The lymph upon the surface of the portions examined was scanty. It was composed of proliferated peritoneal cells, with hardly any fibrin. Amidst the cells were bacilli of various morphological varieties, but mainly short bacilli, singly and in pairs. In some places bacteria with morphological characters of cocci and diplococci were seen, and these coccus forms had begun to penetrate the substance of the peritoneum, although the bacilli were confined to the surface. The peritoneum itself seemed to have undergone hardly any alteration, except that its endothelium was proliferating. I have lately observed another case of septic peritonitis in which the surface lymph contained bacilli and micrococci, and the depths of the peritoneum micrococci alone. In this last instance the micrococci were in chains, and easy, therefore, to identify. The swollen lymphatic glands were more vascular than healthy ones, and the vessels in their hila and along their trabeculae were distended with blood. The lymph paths were very wide and had probably been distended with fluids; some of them, especially those of the cortex, were crowded with leucocytes which retained methyl blue. However, no bacteria could be found in any part of these lymphatic glands, and I think it doubtful whether any were present. I am indebted to Mr. Blandford for much patient labour at this material. Thus in rapidly fatal diffuse septic peritonitis neither the peritoneum nor the swollen lymphatic glands are for many hours in an irremediable state.

OPERATIVE PERITONITIS; PERFORATIVE PERITONITIS.

If my observation is correct—and I know how easy it is to be mistaken—that the peritoneum was infected with both bacilli and micrococci, a point of some interest arises. Waterhouse,⁶ Walthard,⁷ and others speak of "perforative peritonitis" and "operative peritonitis." In the first bacilli are found, in the second micrococci. This generalisation would have been more probable if Beinstock had been right in his assertion that the intestines were only inhabited by bacilli. Escherich has shown, however, by plate cultures that cocci also inhabit the intestines. Culture experiments might easily lead to the inference that the fluid of perforative peritonitis contained nothing but bacilli. On various occasions I have inoculated culture media from the peritoneal fluid in perforative peritonitis. Like others, I have obtained a growth of bacillus coli communis, not because it was the only microbe present, but because the media suited it best. In cover-glass preparations of the exudations in perforative peritonitis many more morphological varieties of bacteria can be seen than can be grown either in the presence or absence of oxygen; indeed, culture experiments taken alone abound in fallacies. In a case of diffuse septic peritonitis due to a perforating ulcer of the duodenum I could see in the exudation: (a) minute bacilli, singly and in pairs; (b) bacilli about the size and shape of tubercle bacilli; (c) short, plump bacilli of some magnitude; (d) cocci and streptococci; (e) saccharomyces; and (f) moulds. Inoculated into broth, this exudation grew short bacilli, in pairs and short chains. Some of the chains might have consisted of streptococci, some of which were seen in the exudation. In the case (Case 2) to which I have just referred we have to consider the possibility of the original infection having been one of micrococci. In this event the bacilli may have emigrated into the lymph which the cocci had produced from, the intestines and after the death of the patient. Before saying anything more about perforative peritonitis I propose to contrast a case of streptococcus peritonitis with those which have just been described.

STREPTOCOCCUS PERITONITIS.

CASE 4.—A girl sixteen years of age was admitted with inflammatory swellings about the right humerus, the lower end of the left radius and ulna, and of the left calf. She also had a distended and tender abdomen, but without sickness or obstruction. She had not been well for three weeks and attributed her illness to a wound of the thumb which she received whilst at work making lace. The scar of a recently healed wound was seen upon the thumb. The swelling about the right humerus was opened, and some greenish pus escaped.

⁶ Prize Essay, Edinburgh. For abstract see Virchow's Archiv, Band cxix., Heft 2.

⁷ Archiv für Experimentelle Pathologie und Pharmacologie, 1892, p. 275.

⁸ Transactions of the Royal Medical and Chirurgical Society, vol. xxviii., 1895, p. 1 et seq.

Soon after the operation she began to vomit and speedily died. During her illness her temperature was usually about 101° F. At the examination, which was made in the winter twenty-six hours and a half after death, the swellings of the arms and legs were noted, and an abscess the size of a hazel nut was found near the root of the tongue, amongst its muscular fibres. The thoracic viscera were normal, except the bases of the lungs, which were congested. The peritoneum was much inflamed and contained a quantity of pus, some of which filled the pelvis. The vagina, uterus, and Fallopian tubes were healthy; but the left ovary contained an abscess as large as an orange, which had burst and, Mr. Berry believes, started the diffuse septic peritonitis. The spleen was large and soft, and the liver covered with punctiform hæmorrhages. The histological examination showed that the surface of the peritoneum was covered with lymph consisting mainly of corpuscles with very little fibrin. (Fig. 4.) This lymph

FIG. 4.

Streptococcus peritonitis. Lymph upon the surface of the peritoneum.

contained vast numbers of cocci, singly, in pairs, and in chains of various lengths. In places these cocci had penetrated far into the substance of the peritoneum and had reached the subperitoneal fat. Here they were thickly crowded in the connective tissue trabeculae between the fat cells. (Fig. 5.) Many of the lymph paths were crowded

FIG. 5.

Streptococcus peritonitis. Streptococci in the depths of the peritoneum.

with vast numbers of cocci, diplococci, and streptococci. The bloodvessels of the peritoneum were engorged with blood, but contained no bacteria. The substance of the peritoneum was comparatively free from cellular infiltration. Here and there the surface lymph had in it leptothrix of slender bacilli.

These were few and scattered, and, I believe, had grown after death. It is to be regretted that the liver, spleen, and other organs were not obtained for examination. Before the history of this case was known to me, and judging solely from the microscopical appearances, I had come to the conclusion that the peritoneum had been infected with streptococcus pyogenes. This is usually found in abscesses and suppurations about the female genital organs, and is also one of the commonest causes of pyæmia. Döderlein and others have shown that vaginal pus usually contains streptococcus pyogenes, often associated with other microbes. Thus the case may have been one in which an abscess of the ovary had existed for some time, and then suddenly burst and caused diffuse septic peritonitis, followed by pyæmia; or the original point of inoculation may have been the thumb; and the abscess in the ovary, like those of the root of the tongue and of the arm, may have been an ordinary pyæmic abscess. Whichever way the ovarian abscess formed, it seems to have been the source from which the peritoneum became infected. The histological appearances support the view that at first the micrococci grew upon the surface of the peritoneum, afterwards penetrated into its substance and into its lymph paths, and finally caused a general infection. It is unnecessary to point out that in such a condition as this our present surgical remedies would be of no avail. The histological examination of this case is, unfortunately, very incomplete. I was only furnished with some portions of the peritoneum. Further knowledge of these peritoneal infections is urgently needed, but it is doubtful whether culture media will supply what is wanted.

STREPTOCOCCUS PLEURITIS; STREPTOCOCCI AND BACILLI IN WOUND.

I have now described several cases illustrating the effects of bacteria upon the peritoneum. I next purpose to describe a case to show their effects upon the pleura, and incidentally their distribution in a large septic wound of the axilla.

CASE 5 (Figs. 6, 7, and 8).—A man aged thirty-nine years, who was strong and well nourished, and with nothing in his appearance to suggest a predisposition to infection, had a large lympho-sarcoma, which filled the right axilla. A severe operation was performed for its removal. At this operation a good deal of blood was lost, but not a very

FIG. 6.

Streptococci in lymph of a septic wound in the axilla.

excessive or very dangerous quantity. Whilst attempting to dissect the growth from the chest wall the surgeon made a small puncture into the pleural cavity, and air was heard to enter and leave the chest. After the operation symptoms of infection soon became manifest. Upon the second day the temperature steadily rose to 102.2° F., with a rapid pulse and respiration, and he seemed much exhausted, but without suffering any pain. A quantity of blood-stained serum ran through the dressing of cyanide of mercury gauze. There was also emphysema of the cellular tissue of the neck and chest. He became gradually

worse and died upon the third day, all the symptoms having gradually become aggravated. The temperature rose during reaction to 104° and fell a little before the end, but rose again during the last hours. The examination showed that the tumour had been partially removed, and that there was a small puncture of the pleura in the third intercostal space. The axillary wound contained a few drachms of thin pus and was covered with a layer of ashen lymph. The whole pleura was covered with a layer of lymph and contained two or three ounces of blood-stained fluid, as did likewise the pericardium. In other respects the body seemed healthy, and no other signs of sepsis were found. The surface of the wound was covered with granular exudative cells, which had also infiltrated the underlying tissues. The exudation was full of cocci, diplococci, and streptococci. (Fig. 6.) Many cocci had passed along the lymph paths and vessels, which had been divided in the incision. Clots in the smaller vessels contained occasional cocci and diplococci, but in the deeper tissues many small vessels were packed with cocci. Amongst these many diplococci and occasional short strings could be made out. (Fig. 7.) The streptococci in the

The lymph upon the surface of the pleura was from one to two millimetres thick. It was composed of exudative cells and fibrin, mixed with vast quantities of streptococci. The latter, unlike those in the axilla, grew in luxuriant chains entwined in dense and entangled masses buried in the lymph. (Fig. 8.) Many chains of cocci projected from the surface of the lymph into the pleural sac. The pleura had undergone the usual inflammatory changes, but these were confined to its surface and the lung was almost unaffected. The kidneys, liver, and spleen were examined for bacterial invasion but none was found. The fatal result was, therefore, caused by a local invasion of the axilla and pleura, and clearly the latter was enough to suffice. It is obvious that this infection might have been conveyed to the wound either during the operation or when the dressings became saturated. However, the temperature had begun to rise before the last event. It seems probable that both the wound and the pleura were infected at the same time, either by the instruments or by the atmosphere. The rapidity of the invasion, the high temperature, and the profound constitutional disturbance are all, I believe, ordinary features of virulent streptococcus invasion. The pro-

FIG. 7.

FIG. 8.

Streptococcus pleuritis. Entangled masses of streptococci in lymph upon the surface of the pleura.

axillary lymph were scattered indiscriminately, and not collected in dense masses such as were found in the pleuritic exudation which I am about to describe. For long I thought that cocci were the only bacteria in this wound; but after many attempts bacilli were found in the lymph and in the tissues next to the wound. These were about the size of anthrax bacilli (Fig. 7), but with rounded ends. They possessed no spores and grew singly and in pairs. They stained by Gram's method, but were seen best by Cenzynke's. The discovery of these bacilli raises several interesting questions. Some might consider that they may have been mere putrefactive bacteria which had grown after death. This may be the truth, but is a pure assumption. Indeed, they are not at all unlike bacillus septicus in their morphological characters, and they also seemed to resemble that anaerobic microbe in another particular. The lymph upon the surface of the wound, where presumably oxygen might be present, was almost free from them, although it contained quantities of streptococci (Fig. 6); the tissues, on the other hand, contained many bacilli, so that it looked as if the latter sought a habitat where there was little oxygen. To me the discovery of these bacilli is very interesting. After many examinations I had concluded that the wound was infected with nothing but streptococci. Probably culture experiments would have hardened me in this belief. It is improbable that a strict anaerobe, such as this bacillus seemed to have been, would have grown by the ordinary methods which I and most others have hitherto adopted. It is evidently rash to make positive statements about the bacteria of any wound upon the mere evidence of cultures.

duction of lymph in the wound and upon the serous membrane is also a common consequence of their activity. In the next lecture I shall describe a similar layer of pleuritic lymph which owed its origin, not to micrococci, but to bacilli. Had bacilli been found in the pleuritic lymph in this case the question would have been much more complicated. It seems reasonable to suppose that the comparative fewness of the streptococci in the axillary lymph and their luxuriance in that of the pleura is explained by the different conditions under which they grew. Various antiseptics were used for the wound, which was also drained; the pleura had none of these applications. In contrasting these two cases of invasion of the pleura and of the peritoneum by streptococci, the most striking difference is the small production of lymph in the peritoneum and its thickness in the pleura. Associated with this we have to notice that the streptococci had penetrated deeply into the peritoneum, whilst the pleura was hardly affected at all. Moreover, it is singular that the streptococci are irregularly scattered throughout the peritoneal lymph and in the substance of the peritoneum itself, but in the pleuritic lymph they are collected into entangled masses of considerable size. (Compare Figs. 5 and 8.) The lymph which covered the pleura had the same physical characters as the lymph which I have produced in rabbits by the subcutaneous application of unsterilised croton oil or unsterilised mercury. This septic lymph differs but little physically from that which is caused by sterilised croton oil, sterilised mercury, or pure carbolic acid. Biologically and chemically the difference is great because bacteria and their

products are present in one case and not in the other. The presence of the bacteria has, when critically examined, a slight but important effect upon the physical characters of the lymph; it is more fluid, its edges are ill-marked and shade off gradually into the surrounding inflammation, and, last, it has hardly any tendency to organise. The lymph which is caused by carbolic acid and mercury in the absence of bacteria is firm and consistent, its edges are abrupt and sharply defined, and if the rabbit be killed a week after the application of the chemical, and injected with carmine gelatine, it may be seen with the naked eye that numerous small vessels have begun to penetrate the lymph. The organisation of some kinds of aseptic lymph seems, as far as I can ascertain, to have been overlooked by those who have worked at this subject. It is, nevertheless, a point of some interest and importance. The conditions under which septic lymph organises or disappears are worthy of inquiry. Recently I opened the abdomen of a boy seven years of age, who had diffuse septic peritonitis due to a perforation of the ileum. The abdomen contained pus and lymph, and much of the latter was left behind. The child recovered, but I have often wondered what became of the septic lymph which was left behind. In another case an incision was made over the cæcum for the purpose of finding the vermiform appendix. This was prevented by recent adhesions, which were so abundant and bled so much that they could not be separated without a great risk of lacerating the bowel. The cæcum was accidentally opened, and six weeks afterwards, when I closed the opening, to my astonishment the adhesions which had been so troublesome had disappeared and the cæcum and neighbouring intestines looked almost normal.

BACTERIAL INVASION OF THE PERITONEAL LYMPH PATHS IN SEPTIC PERITONITIS.

The foregoing observations tend to show that the intestinal bacteria do not, like the streptococcus pyogenes, easily penetrate into the substance of the peritoneum. The following, however, seems to suggest that after time has elapsed even the intestinal bacteria may invade the peritoneal lymph paths. It also illustrates how difficult it is in practice to distinguish betwixt operative peritonitis and perforative peritonitis.

CASE 6.—A man thirty years of age had suffered for five years with symptoms of gastric tumour or ulcer. These culminated in stricture of the pylorus, with dilatation of the stomach and its attendant troubles. To dilate the pylorus an abdominal section was done and an incision made in the front wall of the stomach. When the pylorus had been dilated this wound was closed with a row of sutures in the mucous membrane and another in the serous coat. For a few days the operation afforded some relief, and food was taken by the month. On the seventh day severe pain occurred in the region of the stomach, and upon the eighth day the patient died of septic peritonitis. This was not accompanied by any rise of temperature; indeed, his temperature was usually subnormal. I made an examination twenty-two hours after death, and found that the wound in the stomach had given way. The whole peritoneum was inflamed, with a quart of purulent fluid and stomach contents in the flanks and pelvis. There was much lymph around the wound in the stomach and about that in the abdominal wall, with some suppuration along the sutures. The piece of peritoneum which was examined was taken close to the wound in the abdominal wall. The ulcer in the stomach was not malignant⁸ and the body was healthy, with the exception of what has been described. Histologically⁹ the tissues of the peritoneum had not undergone much alteration. The surface-cells had proliferated and some inflammatory corpuscles infiltrated its substance, but this infiltration was not very marked. Nor was there much congestion of the bloodvessels. Amidst the lymph upon the surface were a great variety of bacteria, cocci, diplococci, and bacilli of various lengths and thicknesses. (Fig. 9.) Here and there the bacteria were collected into groups, and it was difficult to say whether there were swarms of short bacilli or clumps of staphylococci. Similar bacterial forms were seen in the adjacent lymph paths. But in these spaces chains of bacteria were conspicuous. It is difficult to say whether these chains consisted of cocci or of short bacilli. The lymph paths also

contained bacilli of considerable size (Fig. 9). In addition to bacteria they were partially filled with exudation corpuscles, and some material which looked like coagulated albumen, such as is often seen in the renal tubules in certain kinds of acute nephritis. In the depths of the peritoneum, as far as the subperitoneal fat, there were small, dense collections of bodies which had the appearance of cocci and diplococci. These were always arranged round a nucleus and were not contained in any space. I am ignorant of their meaning. Some, I believe,

FIG. 9.

Bacterial invasion of the principal lymph paths in diffuse septic peritonitis.

would call them phagocytes laden with bacteria.¹⁰ The liver and kidneys of this case were also examined, but no bacterial invasion was discovered.

The history of the case leaves a doubt as to whence these bacteria originated. It is possible that they came from the outside, for the wound was septic, or from the interior of the stomach. The contents of the stomach possess a luxuriant flora and could well furnish the bacteria which were found; various articles of diet, the saliva, and the pharyngeal and nasal mucous membranes supply it with a vast variety of bacteria. De Bary's¹¹ work has an important bearing upon this question. He examined the contents of healthy and diseased stomachs. The acid material from healthy stomachs contained hardly any bacteria in comparison with that from cases of cancer of the pylorus, stenosis of the pylorus, or of ulcer of the stomach. Gillespie¹² and Macfadyen¹³ found many varieties, including the bacillus coli communis. At the same time they note that healthy gastric juice has fair antiseptic properties; but Macfadyen and others have remarked that in the contents of the intestinal canal more bacteria can be distinguished microscopically than can be recognised in cultures inoculated from these contents. Barbacci has also tried to show that the bacillus coli communis is of less importance in causing perforative peritonitis than other bacteria which are present, but will not grow in cultures. Thus in the case just given either the stomach or the wound could furnish the bacteria seen in the lymph and in the lymph paths. The number of bacilli, however, suggests that they come from the stomach. The absence of any rise of temperature during the peritonitis also suggests that it was not caused by the ordinary pyogenic cocci. The presence of strings of bacteria in the lymph paths is consistent with what we already know of these kinds of organisms. In erysipelas, cellulitis, and lymphangitis the streptococci travel along the lymph paths, their passage being facilitated by their shape, which is well adapted for narrow channels; on the other hand, clumps of staphylococci

⁸ The specimen is in the museum of St. Bartholomew's Hospital. (No. 1861 b.)

⁹ I am indebted to Dr. Addison for much labour at these tissues. Our most successful specimens were stained with alkaline methyl blue.

¹⁰ These specimens were stained with alkaline methyl blue.

¹² Bacteria of the Stomach: Journal of Pathology, vol. 1, p. 294.

¹³ Journal of Anatomy and Physiology, vol. xxi., 1886, p. 237.

or of bacilli would, it might be supposed, find it difficult to pass along the narrow channels of the tissues. Thus we find that such an organism as *staphylococcus aureus* is usually associated with acute localised suppurations or inflammatory wound gangrene (Ogston), and *streptococcus pyogenes* with spreading inflammations such as erysipelas or cellulitis.

INTESTINAL BACTERIA IN OTHER CONDITIONS: HEPATIC ABSCESS.

During these investigations I have met with intestinal bacteria in other diseases besides perforative peritonitis, and it may not be out of place to refer to these occurrences. For instance, the following¹⁴ illustrates their presence in abscess of the liver.

CASE 7.—A man who had lived six months in India and had had ague and dysentery there, returned to England, and had an attack of hepatitis in August, 1887. This seems to have subsided, and to have been followed by a second attack of dysentery and a fresh hepatitis in June, 1892. The abscess in his liver probably dates from this time. In February, 1893, Dr. Norman Moore diagnosed an abscess of the liver and obtained some pus from it with a sterilised needle and after proper disinfection of the skin. Having been called in to open the abscess, I performed laparotomy. As the liver was not adherent it was stitched to the edges of the wound, and forty-eight hours later the abscess was opened. The patient made a good recovery. Cultures inoculated from the wound before opening the abscess remained sterile; others inoculated from the pus grew the bacillus coli communis in pure culture. The pus was very thick and of a slightly greenish tinge, and occasional short bacilli could be seen in it, but living plasmodia were not looked for. The amoeba coli was not sought for in this pus when it was fresh, but none could be seen in stained specimens. My colleague Dr. Galloway,¹⁵ who has done good work at this subject, showed me the amoeba coli in the pus of a hepatic abscess which I opened for a patient of Dr. Clifford Beale. I have recently failed to find the amoeba coli in an empyema of the gall-bladder. The pus contained *streptococcus pyogenes*, and possibly other organisms.

The exact relation of the bacillus coli communis to hepatic abscess has been much debated by Kartulis, Councilman, Ostler, Manson, Galloway, and others, and will not, I venture to think, be decided by mere clinical or bacteriological evidence. Experimental pathology may, however, be expected to throw light on this question. Zancarol¹⁶ performed a series of experiments by injecting dysenteric evacuations, hepatic pus, and cultures from hepatic pus into the recta of cats. These are, so far as I can tell, the only direct experiments upon this disease. Zancarol claims that any of these may produce dysenteric ulceration of the intestine with accompanying abscess of the liver. He seems doubtful whether the amoeba coli causes abscess of the liver in dysentery. He attributes potent effects to streptococci. Although the following experiments performed upon rabbits teach but little, yet they show that the relationship of the intestinal bacteria to abscess of the liver is not so simple as at first glance it seems to be. I mention them here because they may be of help to others—at least by telling them what to avoid. Laparotomy was performed upon a healthy rabbit and a loop of intestine drawn out. Two cubic centimetres of a broth culture of bacillus coli communis, grown from the case of liver abscess which has just been described, were injected into the mesenteric vein. The animal died during the night, and slight peritonitis was found. The animal seems to have been poisoned by the culture. Next, the liver of another rabbit was exposed, and one cubic centimetre of a broth culture of the same bacillus was injected into it. At the end of a week the animal, which seemed to be fat and well, was killed. The injection appeared to have produced no result, but the presence of numerous psorospermal foci forbade any positive statements; at all events, no larger abscess or destruction of liver substance had occurred. The injection of a solution of rabbits' faeces in water into the mesenteric veins of another rabbit made the animal ill, and when it was killed at the end of a week there were found to be several small abscesses at the periphery of the liver; but here again the result seemed uncertain because so many

psorospermal foci were present. These experiments made me think that something more than intestinal bacteria were required to cause hepatic abscess.

INTESTINAL BACTERIA IN OTHER CONDITIONS: TYPHOID ABSCESS.

It is now so well known that the typhoid bacillus can cause abscesses that a case in which that occurred would hardly be worthy of record if it did not also illustrate another point—namely, that bacteria may continue to live in the human body for months or years. This is shown by a case in which I found the typhoid bacillus in an abscess a year and three months after an attack of typhoid fever. The interval which elapsed between the infection and the discovery of the bacillus in an abscess was, I think, clearly substantiated. The patient was a young woman aged nineteen years, who came with a subacute abscess over the front of the tibia. It contained ordinary thick, dirty-yellow pus. The cells of this pus were degenerated, and amongst them were some bodies which were taken to be short bacilli. These grew upon gelatine with all the ordinary characters of typhoid bacilli. The gelatine was not liquefied, and the bacilli grew upon its surface in greyish white layers with irregular edges. In the depths it formed fluffy colonies. The growth was slow at summer temperature. The bacilli were about four times as long as they were broad, with rounded ends and with spores which did not cause any bulging; they grew occasionally in short strings of four or five elements. This patient said she had been liable to abscesses ever since she had been in hospital for typhoid fever. Dr. Goodall has kindly informed me that she went into the fever hospital on April 4th, 1892, with typhoid fever, and that whilst there her case was complicated with abscesses in the axilla and neck. The abscess from which I obtained the pus was opened on June 17th, 1893—at least one year and three months after the onset of the disease. It is so unlikely that this patient could have had a fresh infection with typhoid bacilli that I think we must conclude that those found in the abscess must have lived in her body for at least a year and three months after their introduction. During the greater part of their sojourn they seemed to have caused but little inconvenience to their host. With the exception of the subacute abscess, her health was good. The bacilli seem to have been living for months at the place where they afterwards caused the abscess, and had not been recently deposited there from the blood. The note says that during the months which preceded the abscess its site was occupied by a painful swelling which appeared and disappeared several times.

The typhoid bacillus seems particularly fitted for throwing light upon the question how long bacteria live in the body. Its early effects are so palpable that there is seldom much doubt as to the approximate date of the inoculation. Instances similar to that which I have recorded have been published by Hintze¹⁷ and others, but none of the cases seem to have lasted so long after the fever. In Hintze's case the bacillus was found in an abscess of the chest wall two months after the fever; Werth found them in an ovarian cyst eight months after; Orloff found them in an abscess over the tibia six and a half months after; and others have found them at shorter times. It seems reasonable to suppose that other bacteria may lurk unnoticed long after their introduction. I ought to add that *staphylococcus pyogenes aureus* and the bacillus coli communis have been found in the abscesses which follow typhoid fever.

The Arris and Gale Lectures

ON

THE CENTRAL NERVOUS MECHANISM OF THE RESPIRATION.

*Delivered before the Royal College of Surgeons on
Feb. 22nd, 1895,*

By WALTER SPENCER, M.S., M.B. LOND.,
F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AND TO THE THROAT DEPARTMENT, WEST-
MINSTER HOSPITAL; LECTURER ON PHYSIOLOGY IN THE
MEDICAL SCHOOL.

LECTURE III.

THE RESPIRATORY CENTRE IN ASPHYXIA.

GENTLEMEN,—Carbonic acid excites the respiratory centre, at first causing hyperpnoea by over-action of inspiratory muscles, and later dyspnoea with over-action of expiratory muscles. But the third stage of asphyxia is not due entirely to carbonic acid poisoning. The centre is suffering from want of oxygen owing to the failure of the circulation. Carbonic acid first excites the vaso-motor centre to over-action, and the blood pressure rises. But it soon paralyses the vaso-constrictor influence, and the blood pressure rapidly falls. In the same way carbonic acid excites the cardio-inhibitory centre and the heart is first slowed; but subsequently it acts on the heart and weakens the muscles. The failure of the circulation is therefore due to a paralysis of the vaso-motor centre and of the heart muscle. If a dog be deprived of air for less than four minutes it may spontaneously recover. After this period the heart is found to be beating slowly and feebly, and the blood pressure has sunk very low. The heart may continue to beat for six minutes after the cessation of breathing. The ventricles cease to beat before the auricles, which may go on for a little time longer, the beats being irregular, intermittent, or periodic.

In connexion with this continuance of the heart beat in asphyxia I am happily able to quote some experiments made by a past President of this College, Sir J. Eric Erichsen,¹ which he carried out under Professor Sharpey. The thorax of a dog being opened and the beat of the heart watched, the restoration of the heart and blood pressure always followed upon inflation of the lungs so long as the ventricles had not quite ceased to beat. He never succeeded in restoring the circulation of the animal by artificial respiration of air alone when once the ventricles had definitely stopped. The auricles might start a rhythmic beat, but this did not lead to the ventricles doing so. Nevertheless, when the heart of an asphyxiated animal had quite ceased to beat the artificial respiration of air changed the colour of the blood in the pulmonary veins, the left ventricle, and the coronary arteries, so that it became red, whereas the blood on the right side of the heart and elsewhere remained black. Following the clue given by the last experiment he used oxygen instead of air for inflation. He watched the heart of an asphyxiated animal until all movements had entirely ceased for two minutes, and then commenced inflation with oxygen. The blood in the pulmonary veins, left ventricle, and coronary arteries, as in the last experiment, became red, and in some of the animals the heart began to beat and the circulation was restored. These are the only experiments with which I am acquainted in which the possibility of starting the heart after it has once ceased has been shown in a way which can be applied to man.

In a patient who has ceased to breathe, but in whom the pulse is of full tension, although it may be slowed in rate, we may direct our attention to the removal of the causes of inhibition. Inhibition by afferent stimuli practically occurs from the pharynx or larynx, and breathing may start on the removal of foreign bodies, mucus, blood, or on drawing forwards the tongue, which has fallen back. This inhibition may also be neutralised and overcome by an afferent stimulus

exciting inspiration. One of the most efficacious of these stimuli is that produced by drawing forwards the tongue, especially in rhythmic manner. Laborde² has recorded sixty-three successes by this plan. Presumably the effect is produced by the excitation of the fifth (lingual) or upper roots of the vagus (glossopharyngeal). There are also many other forms of excitation through sensory nerves which may evoke respiration; but if the patient has passed into the stage of asphyxia no effect can be expected from sensory excitation. In such a case artificial respiration and warmth offer the only means of improving the heart-rate and of increasing the force of the vaso-motor centre. When the vaso-motor centre has regained its control of the vessels it reacts to carbonic acid. On cessation of artificial respiration if the blood pressure rises one can with certainty predict that in a few seconds normal breathing will begin. Conversely, if on stopping artificial respiration the blood pressure begins to fall normal breathing will not occur. With regard to recovery in a person apparently dead, in whom breathing has not occurred for five minutes or more, we must conclude that the heart can in such cases only continue to beat when the production of carbonic acid in the tissues has been reduced to a minimum. Cases of recovery after long submersion can be explained by supposing an injury to the head, cold, shock, alcohol, or other cause to have greatly depressed internal respiration at the time of submersion. A man may thus remain under water reduced to the state of a cold-blooded animal. Very little carbonic acid passes from the tissues into the blood, and thus there is not sufficient carbonic acid to poison the heart muscle. Cases of submersion for as long even as half an hour have been followed by recovery.

Poisons other than carbonic acid may affect the respiratory centre, or their action may be combined with that of the carbonic acid imperfectly removed. Cocaine painted on the floor of the fourth ventricle³ paralyses the respiration, and, being washed away by salt solutions, its effect passes off and normal breathing is resumed. Chloroform and ether act in the same way when directly applied to the bulb.

[The lecturer here referred to the dangers of chloroform anaesthesia. He continued:]

There are more rapidly fatal poisons, such as hydrocyanic acid and carbonic oxide gas. Even in such cases recovery is possible if oxygen can be administered early enough and the carbonic acid got rid of. Haldane⁴ placed a mouse in a stream of carbonic monoxide. The animal became distressed, panted, and fell on its side, whilst the tips of its ears became brick-red in colour. If at this point a stream of oxygen were passed into the vessel containing the mouse the animal quickly gets on its legs and appears as well as before. Opportunities of applying artificial respiration and oxygen are, of course, not likely to occur frequently, for the man is generally burnt in the case of the carbon monoxide, and in suicide by hydrocyanic acid the person is alone. Opium, morphine, and chloral act more slowly, and therefore the application of means to excite the respiratory centre will be of much more service. There is a great resistance to these narcotics on the part of animals exposed to heat, and I need not remind you that it is of no use to administer oxygen in a case of failing respiration unless at the same time the carbonic acid be got rid of by artificially aiding the expiration. As to curare, when ozone is passed through a solution of it the substance loses its poisonous properties. It has, therefore, been conjectured that the action of curare may be to snatch oxygen from the nerve substance. A case is recorded of failure of respiration after a puncture by an instrument smeared with this drug. Recovery ensued after two hours of artificial respiration. Strychnine is no stimulant of respiration. When given in a sufficient dose it opposes inspiration by acting chiefly on the nerve roots of the spinal cord which supply the muscles of extraordinary expiration. It is the excessive and inordinate action of these muscles which opposes the inspiratory action. Thus the respiratory centre becomes asphyxiated by excess of carbonic acid, whilst the abdominal muscles are violently contracted in each spasm. The indications for treatment are therefore two—the depression of the over-action of the expiratory muscles by narcotics whilst the respiratory centre is prevented from being asphyxiated by artificial respiration with oxygen. This method of treating a case of strychnine poisoning or of tetanus is obviously a difficult matter.

THE RESPIRATORY CENTRE UNDER INCREASED INTRACRANIAL PRESSURE.

The circulation through the centre may be impaired by cutting off the main supply or by resisting its entrance to the bulb by increasing intracranial pressure. The result is the same in the two cases—at first excitatory and secondly paralytic phenomena. The first effects of severe hæmorrhage are panting and deep inspiration.⁵ Indeed, compression of the carotids is sufficient to cause quickening of the respiratory rate.⁶ The skull is a cavity which is closed except for veins, lymph channels, and the communication with the spinal cord. The subarachnoid space is continuous with the ventricles by the lymphatics of the pia mater and through the brain substance with the spaces in which the cells lie. It also communicates with the venous sinuses. The pressure of the cerebro-spinal fluid is therefore intermediate between the blood pressure in the capillaries and that in the veins—viz., about 10 to 15 mm. Hg; and it can be seen to form as beadlike drops upon the pia mater, which has been first dried. Salt solution infused into the subarachnoid cavity is rapidly absorbed. Respiration is unaffected by the free exposure of the subarachnoid space. A slight diminution in the contents of the cranium—e.g., by a blood-clot or foreign body—may be compensated by a displacement of an equivalent amount of fluid into lymphatics or into the spinal cord, the fluid being squeezed out of the brain as water from a sponge. If a little pressure be applied slowly it may be borne without causing symptoms. If the pressure be applied suddenly symptoms which at first occur may disappear as soon as fluid has had time to escape. When from previous disease the exit by the lymphatic channels has been partly blocked by some inflammatory condition the slightest increase of intracranial pressure has set up a severe obstacle to the circulation through the vital centres. The results of a series of experiments on intracranial pressure have been published in a paper by Mr. Horsley and myself.⁷ A classical experiment, which consisted in setting up intracranial pressure sufficient to affect the bulb, was made by Sir Astley Cooper.⁸ He trephined a dog and pressed with his finger upon the dura mater. The dog became insensible, then comatose, and the pulse slow. When the pressure was released the animal recovered. We employed chiefly a thin rubber bag inserted through a trephine hole which was then filled by mercury. By this means we could raise or lower the pressure, estimate the amount of diminution in the contents of the skull by the amount of mercury running into the bag, and regulate exactly the pressure required by the height of the mercury column above the level of the skull. In dogs of medium size we found with Duret⁹ that the cranial contents could be diminished as much as 5 c.c. without any marked symptoms except an increase in the anæsthetic state of the animal. Whatever may be the slighter effects of intracranial pressure in the direction of local excitation, they were practically excluded by the anæsthesia employed; indeed, they are unimportant for the subject under consideration as compared with the mass displacements of the brain. The pressure applied to any part of the cerebrum tended to displace it backwards upon the cerebellum and bulb. This could be lessened or avoided by removing part of the occipital bone. The cerebellum bulged through the hole and the symptoms of pressure were diminished. We obtained symptoms of an identical character by direct pressure on the bulb, and there we were able to differentiate the cardiac from the respiratory effect.

The effect of increased intracranial pressure was primarily excitatory, causing inspiratory spasm, and finally paralytic, as shown by a diminution in amplitude, a slowing of the rhythm, and finally by arrest of respiration. A similar excitation caused slowing of the heart with a fall of blood pressure. After the arrest of respiration the heart greatly slowed and tended to stop. If the intracranial pressure was immediately taken off recovery ensued in the following order: (a) recovery of heart-rate, (b) rise of blood pressure, and (c) starting of respiration. If the intracranial pressure was severe and rapidly applied, the heart might be momentarily checked as by a strong excitation of the vagus nerve. Then the heart recommenced by slow excursion, which died out as the carbonic

acid in the blood increased. If, however, artificial respiration was carried out the gradual paralysis of the cardio-inhibitory centre could be seen. The heart beat more rapidly and the blood pressure rose as if the vagi had been divided. This rise of blood pressure was due not only to the cardio-inhibitory paralysis, but also to excitation of the vaso-motor centre, for additional intracranial pressure caused a further rise; we obtained extraordinarily high blood pressure after the removal of the cardio-inhibitory influence. Frequently the blood pressure rose to 300 mm. Hg—i.e., was doubled; but the highest reached in several experiments in the dog was 400 mm. Hg. This rise of blood pressure acted as a direct stimulus to the respiratory centre. Breathing frequently began again in spite of the continuance of the intracranial pressure which had immediately arrested it when the blood pressure was at its normal level. But the rise of blood pressure was only temporarily maintained. If the intracranial pressure was continued the blood pressure soon fell to 30 mm. Hg, indicating paralysis of the centre. When pressure is applied directly to the upper end of the spinal cord there is arrest of respiration without the heart being affected, supposing artificial respiration to be soon begun. When the pressure is applied in the upper part of the fourth ventricle the heart may be slowed down, whilst the respiratory rate is retained or even accelerated—i.e., an excitation of both centres. When the pressure is applied to the lower part of the fourth ventricle the respiration tends to be inhibited and the heart slowed. This is the general effect of intracranial pressure by an excitation of the cardio-inhibitory centre with an inhibition of respiration. Collapse or shock was obtained not only as the effect of severe intracranial pressure, but also followed a number of the different kinds of excitation which I have described. Many of the animals have brought the experiment to a conclusion by more or less suddenly lapsing into a condition of low blood pressure, feeble heart, and a respiration characteristic of the third stage of asphyxia. But the condition differs from asphyxia in not being easily amenable to artificial respiration. We have here a rapidly occurring vaso-motor paralysis by means of afferent stimuli through the respiratory apparatus.

Many cases which have been described show the importance of the removal of intracranial pressure. Thus¹⁰ a man who had dislocated his atlas vertebra was found senseless with respiration slow and interrupted, the pulse scarcely to be felt, and paralysis of the spinal cord below. The dislocation being reduced with an audible snap the man soon got well. A similar case under Mr. Horsley of pressure on the upper part of the spinal cord from caries of the spine had not only paralysis of the spinal cord but stertorous breathing. After laminectomy respiration immediately became free, and the boy regained the power to walk. Other cases in which respiration only has failed would have been, as proved post mortem, amenable to surgical interference. Thus in one case artificial respiration was continued for twenty-four hours, during which the heart beat strongly, and it did so for a few minutes afterwards. On post-mortem examination a cerebellar abscess was found. In another case artificial respiration was kept up for six hours, and a cerebellar abscess was afterwards found. In a third artificial respiration was performed for eight hours and a half; the pulse, at first strong, gradually became feebler (vaso-motor paralysis) and finally ceased. A cerebellar cyst was found. I have mentioned these to emphasise the importance of surgical exploration in order to try to relieve the pressure.

Intracranial pressure may arise from hæmorrhage. If the hæmorrhage comes to a standstill a similar amount of cerebro-spinal fluid may be absorbed, and so the symptoms be relieved. It is, therefore, of the first importance to arrest the bleeding. A compression or ligature of the external carotid may stop extravasation of blood from the middle meningeal artery. In conjunction with Mr. Horsley I have published a paper,¹¹ in which it was pointed out that the circulation through the middle cerebral artery, and especially through the lenticulo-striate artery of the monkey could be so controlled by compression of the carotid that a clot soon forms and blocks the mouth of the artery. We pointed out that as the lenticulo-striate artery is practically the continuation upwards in a straight line of the internal carotid, it must receive more of the force of the blood stream than the rest of the circle of Willis. Herein lies the reason why it is so frequently diseased as to be the

cause of 70 per cent. of cases of apoplexy. Being therefore the continuation of the internal carotid the circulation through the vessel is particularly weakened by compressing the carotid. We suggested that these experiments might point to the employment of compression or ligature of the common carotid artery in cases of ingravescent apoplexy. The suggestion has been taken up in America, and one of two cases appeared to have been benefited; at any rate, the ingravescent apoplexy was cut short.¹² During this week Dr. Washbourne has sent me the notes of a case under his care in Guy's Hospital. The patient had the symptoms of progressive hæmorrhage from the lenticulo-striate artery, and Mr. Dunn ligatured the common carotid. The hæmorrhage was apparently arrested, but there were severe pulmonary and renal complications. Death ensued two days afterwards. Where hæmorrhage has already occurred from the middle meningeal, the clot has been forced out of the trephine hole, showing the great pressure under which it was placed. Whether the removal of an apoplectic clot will be found practicable I do not know. Until the mouth of the ruptured vessel be plugged hydrodynamical conditions keep the clot under the same pressure as that of the blood-pressure, the latter being in the early stages far above normal. In any case it must be remembered that it is the failure of respiration which first happens, and artificial respiration may keep the centre and the heart from asphyxia until sufficient fluid has escaped from the brain to compensate for the room occupied. In such cases not only may cerebro-spinal fluid be removed, but the blood serum may be gradually absorbed and the blood-clot occupy so much less space as to allow respiration to start again.

RHYTHMIC AND PERIODIC (CHEYNE-STOKES) RESPIRATION.

Spontaneous rhythmic movement is a fundamental property of protoplasm as seen in the pulsating vacuole of a protozoön. Nerve cells originate rhythmic movement—e.g., the ganglion cells in the margin of the bell of a medusa. The rhythmic respiratory movements in the larvæ of some insects—e.g., *Libellula*¹³—may continue in detached segments, provided that one pair of the ventral chain of ganglia be included in the separated segment. Sir James Paget long ago expressed the belief that rhythmic motion is an issue of rhythmic nutrition. Rhythmic movement becomes periodic when the nutrition of the cells is failing, and is thus seen in the dying heart. Periodic respiration may depend upon periodic variations in the blood-supply, or in a prolongation of the time taken for the building up of a hypothetical inogen before kinetic energy can be liberated in the shape of an inspiration. Periodic respiration is seen in the deep sleep of young children and animals after the administration of somnific doses of morphia and chloral. A small amount of intracranial pressure in an anæsthetised dog may cause the respiration to become periodic. This kind of periodic respiration may occur in patients, and forms an incomplete type of Cheyne-Stokes respiration without the apnoic pause. Marked cases of Cheyne-Stokes respiration¹⁴ have never, so far as I know, been produced experimentally. It is an extraordinary phenomenon, especially the placid, almost anæsthetic state of the patient during the apnoea, as compared with the excited, sometimes even distressed, state of the patient when respiration has reached its maximum. In producing periodic respiration in animals exaggeration of the vaso-motor or Traube's curves may be noted as occurring at the same time. This variation in blood pressure may be sufficient to influence a weak respiratory centre. Recovery may ensue even when Cheyne-Stokes breathing has existed for months. In asphyxia, exhaustion, or after partial destruction of the bulb, where the animal is dying and the respiration of the kind which occurs in the third stage of asphyxia, there may be seen a periodicity of short inspirations or gasps. This periodicity perhaps arises from delay in the building up of the hypothetical inogen.

In these three lectures, gentlemen, I have brought before you such parts of the subject as have appeared to me to yield matter of practical value. Lack of time, insufficient evidence, and difficulty in forming conclusions are my reasons for passing over the rest without reference. I have to thank the President and Council of the College and the Curator for the opportunities afforded me for lecturing on the subject.

A CASE OF PERFORATION OF THE GALL-BLADDER FOLLOWING TYPHOID FEVER SUCCESSFULLY TREATED BY ABDOMINAL SECTION.

By MONTAGU S. F. MONIER-WILLIAMS, L.R.C.P. LOND.,
M.R.C.S. ENG.,

AND

A. MARMADUKE SHEILD, F.R.C.S. ENG.

ASSISTANT SURGEON TO, AND LECTURER ON PRACTICAL SURGERY AT,
ST. GEORGE'S HOSPITAL.

Remarks by Mr. Monier-Williams on the medical history of the case previous to operation.—I was called on Sept. 18th, 1894, to see a married woman aged thirty-one years. She complained of pains all over the body, especially in the legs, severe headache, sleeplessness, and great weakness. The family history was unimportant. In connexion with her previous health was noted the fact that in 1883 she had a very severe attack of sudden abdominal pain accompanied by shivering fits, for which she was attended by Sir Francis Laking. The present illness commenced on Sept. 13th with headache, sore-throat, aching of the limbs, and shiverings; and the same symptoms persisted until I saw her five days later, when she had taken to her bed for the first time. I then found the temperature 103.5° F., the pulse 120, compressible, and dicrotic, and the tongue moist with a thin white coating. There was profuse perspiration and intense weakness. Percussion and auscultation showed the heart and lungs to be normal. The respiration was 20 to the minute, and there was fair abdominal breathing. The appetite was bad, and there was great thirst and much flatulence. Slight distension of the abdominal walls was present, and there was some tenderness in the right iliac fossa, but no abdominal pain. The spleen was enlarged and tender, and could be felt below the costal margin. The bowels had been slightly confined since the commencement of the illness. The urine on examination was found to be normal. A small dose of calomel was ordered, and an effervescent citrate of ammonia mixture. The next day, Sept. 19th, the bowels were freely open, and the motions were loose, of a yellow ochre colour, and very offensive. During the next two or three days the temperature oscillated between 102.5° and 103.5°, the pulse remained at about 120, the bowels were open once daily, the motions being of the same character as above, and the diagnosis of typhoid fever was made. On Sept. 21st, the ninth day of the disease, three or four pink spots appeared on the abdomen, but they were not sufficiently characteristic of the rose rash of enteric fever. On Sept. 23rd, the eleventh day of the disease, the patient was seized early in the morning, quite suddenly, with acute pain in the abdomen, and I was at once sent for. On arriving I found her in a semi-collapsed condition, with feeble, fluttering pulse and cold, clammy skin, complaining of agonising pain in the abdomen. The temperature shortly before the commencement of the pain was 102.5°, but now, two hours later, had fallen to 99°. Abdominal breathing was practically absent. The pain was diffused over the upper part of the abdomen, a spot a little above the umbilicus being perhaps the seat of its greatest intensity, and there was considerable tenderness in this situation and over the region of the ascending colon. I considered the possibility of a perforation of the intestine, even at this early date, and ordered opium freely and stopped all food by the mouth. A little later in the day Dr. Isambard Owen kindly saw the patient in consultation with me. She was then much relieved of her pain, the tenderness was less, and there was some slight abdominal breathing. Dr. Owen thought that the case was probably one of typhoid fever, and that we had to deal with an intestinal perforation, though possibly not a complete one. Opium was now administered less freely, but the patient was still fed only by the rectum. Twelve hours after the onset of collapse the temperature rose to 104.5°, the highest point reached during the illness. In a few days' time all pain and tenderness had disappeared. Opium was discontinued, and on Sept. 27th, the fifteenth day of the illness, nourishment was taken by the mouth again in the ordinary way. The case was now taking the course of an apparently moderately severe case of typhoid fever without complications. There was a gradual fall of temperature towards the close of the second week, but a rise

again occurred, and during the third week the evening temperature varied from 102° 5' to 103° 5'. During this period of the illness the pulse kept at about 110, and was small and easily compressible; the bowels were inclined to be confined, the motions being sometimes quite loose and sometimes almost formed, but always very offensive and of a yellow ochre colour. The patient suffered from profuse perspirations, slept very little and occasionally wandered at night, and was much prostrated. The tongue was surprisingly clean and fairly moist, and was not like the dry-coated tongue generally seen in enteric fever at this stage. The treatment consisted of a pill of two grains and a half of thymol three times a day. My partner, Dr. Weldon, attended the patient for a few days at this time, and concurred in the diagnosis of typhoid fever. During the fourth week of the illness the temperature fell gradually by lysis, and at the end of the week reached the normal, where it practically remained for the ensuing fortnight except for a slight temporary rise towards the end of the sixth week due to faecal accumulation, and which subsided directly the bowel was thoroughly emptied by means of an enema. The stools were now much less offensive, but still rather light in colour. On Oct. 28th the patient was practically convalescent. The abdomen was natural in every respect, there being nothing abnormal to be made out either on palpation or percussion. The bowels were acting regularly, and the temperature having been normal for a fortnight, solid food was cautiously commenced. During the night of the 29th the patient experienced some slight abdominal pain, but not severe enough to keep her awake. On the morning of the 30th, however, I found her suffering from severe pain, which she referred to the region of the hepatic flexure of the colon, and here there was considerable tenderness. Later in the day the pain was much worse, shooting through to the back, and the temperature had risen to 101° 2'. The pain was still limited to the region above mentioned, and there was now an area of about the size of an orange decidedly dull on percussion and very tender. Opium was freely given and rectal feeding ordered. Later in the evening Dr. Whipham saw the patient in consultation with me, and the question of a possible intestinal perforation was again discussed. Dr. Whipham was not inclined at that particular moment, however, to take such a serious view of the case, and thought that faecal accumulation would account for the symptoms then present. The next morning (Oct. 31st) the patient was much worse. There was decided distension of the abdomen and signs of a localised peritonitis in the right hypochondrium. The temperature was 102° and the pulse 140, feeble and running in character. Later in the day the temperature had risen to 103°, and judging that abdominal section might be expedient I asked Mr. Sheild to see the patient with me. Before proceeding to the joint report of the subsequent surgical treatment of the case I would note the following points of interest. The temperature chart, although fairly typical of enteric fever, was not absolutely so, the morning remissions of temperature being greater than we are accustomed to see. The tongue, as above stated, had only a thin white coat and was moist; but this, experience shows, is not uncommon in typhoid fever. Finally, as to the sudden attack of abdominal pain with collapse on the eleventh day of the disease, are we justified in considering this to have been due to an incomplete intestinal perforation, or was it caused by some similar condition of the gall-bladder, which temporarily healed, but subsequently relapsed into the state shown by the operation to be present, and shortly to be described? An intestinal perforation as early as the eleventh day is rare, but Dr. Osler has recorded more than one case at the eighth day. It is also perhaps worth noting that the patient ate freely of oysters sixteen days before the onset of her illness.

Conjoint report by Mr. Monier-Williams and Mr. Marma-duke Sheild.—When we saw the patient together on the evening of Oct. 31st her condition was very serious. The abdomen was tympanitic and exquisitely tender, especially over the right side. The seat of most acute pain and tenderness was to the right and above the umbilicus. The temperature was 103° and the pulse 140, very weak and with that well-known running character which so often heralds approaching death. The extremities were not cold, the tongue was clean, and the patient was rational and could converse. The face was pinched and anxious, but lacked the appearance of death-like collapse so generally noticeable in perforation of the intestine from typhoid ulceration. Here it may be observed that the patient was well under the influence of opium. No flatus or faecal matter had lately passed per rectum. Every-

thing seemed to point to perforative peritonitis, but it seemed to us that to subject her to an abdominal section while the pulse manifested the symptoms above described was perilous in the extreme, if not hopeless. We also could not but reflect that she had recovered from a similar though, of course, less severe attack before, and we then determined to wait until the morning. Nutrient enemata with laudanum were given through the night. We saw her early on the morning of Nov. 1st. She then seemed somewhat better, and the pulse though rapid was stronger. The abdominal conditions were worse. The abdomen was more tympanitic, the abdominal walls being quite motionless. After anxious consideration it was now determined to operate, and we were inclined to the belief that a perforation in the small intestine would be found. The operation was performed at twelve o'clock on Nov. 1st. Mr. Arthur Ward assisted, and Dr. Grant Morris administered an anæsthetic mixture. It was difficult to carry out under the circumstances all the elaborate technique of an aseptic abdominal operation, but we aimed at doing our best. Very few instruments were employed, and these were boiled and immersed in 1 in 20 carbolic solution. The skin of the abdomen was cleansed with soap and water and sponged with the same lotion, and the limbs were swathed thickly with cotton-wool. Nine sponges only were employed to simplify counting and after recognition. A free abdominal incision was at once made in the median line commencing above the umbilicus, and the cavity was opened without delay. The distended intestines were received in a warm towel by Mr. Ward, and held over to the left side. It was at once obvious that the most acute focus of inflammation was situated in the right hypochondriac region. The intestines here were much blown up, red and congested, and covered with purulent lymph, while among their coils some free turbid fluid could be seen welling up posteriorly. The incision was extended upwards to the under surface of the liver, where was much purulent lymph matting the tissues together. Believing that a perforation existed towards the upper part of the intestinal canal, diligent search was made, but none could be detected, and while disentangling the adhesions and sponging away the soft lymph under the liver the gall-bladder came into view, and its appearance was peculiar and suggestive. This viscus was deeply inflamed, of a dark-plum colour, rigid, thickened, and adherent, but not much enlarged, though tightly distended. The source of mischief was soon apparent, for low down near the neck of the gall-bladder was a sharply circular, sloughy ulcer the size of a threepenny piece. Its floor was bright yellow, and it was surrounded by a vivid red zone of intense hyperæmia. On stroking it with the probe fluid escaped at one spot, showing that leakage of the contents had already occurred. A fine trocar was now introduced, but to our surprise nothing escaped, and the gall-bladder was opened at its fundus by a stroke from the scissors. About one and half ounces of thick, offensive pus, not mixed with bile, were evacuated into a glass held in the abdominal cavity, sponges being packed round to prevent further contamination of the peritoneum. The gall-bladder was obviously converted into a suppurating sac, probably cut off from communication with the biliary flow. The viscus was cleaned out with pledgets of wool held in the forceps, and a careful search made for a calculus by a probe internally and the finger externally. Nothing of the nature of a stone could be detected, and it was uncertain what caused the closure of the cystic duct. The tissues were so rotten that the probe was used with much caution, and no prolonged attempts were made to pass it into the common duct. The sloughy ulcer near the neck of the gall-bladder had now quite given way, and I (Mr. Sheild) tried to unite it after the Lembert method; but the stitches cut their way out persistently, though deeply placed. It was obvious that the gall-bladder was too soft and lacerable to deal with, still less to bring it to the surface the abdominal wound. So much time had already been expended that the idea of its complete removal was out of the question. The wound in the fundus was therefore attached to the parietal peritoneum, and the parts under the liver cleansed by flushing with warm water and repeated sponging. An incision was made at right angles to the former, reaching towards the right lower ribs, to allow of more dependent drainage. The next step was to deal with the intestine. A fine trocar was introduced into the enormously distended ascending colon. The puncture was made obliquely, running for some distance along the longitudinal bands before perforating the mucous membrane. A large quantity of flatus escaped, aided by

Mr. Ward manipulating the intestine towards the puncture. By this means the intestines were flattened, and after further cleansing were returned to the peritoneal cavity. A glass tube was now passed deeply into the lesser cavity of the peritoneum, and a long and liberal slip of carbolised gauze was firmly packed round it so as to flatten the now empty gall-bladder against the under surface of the liver, and shut off the intestine from contact. The abdominal wound was closed with all rapidity with fish-gut sutures and varnished over with collodion, being finally covered with a cyanide gauze dressing. The operation lasted exactly one hour, and at its expiration the condition of the patient was satisfactory; indeed, after the hot-water flushing the pulse somewhat improved.

In the after-history of the case we wish as far as possible to be brief, only mentioning the more important particulars and purposely omitting minute references to all the variations of pulse and temperature, and modifications in dietary, which are so essential to observe in the treatment of cases of abdominal section. On the evening of Nov. 1st we found the patient suffering from considerable collapse; she had vomited urgently several pints of greenish fluid. The pulse had fallen to 108 from 148 before the operation, and the temperature was reduced to 99.8°. Small nutrient enemata containing laudanum were ordered at frequent intervals and half-grain doses of opium by the mouth. The sickness continued through the night and the greater part of the next day, when it somewhat abated. On Nov. 3rd the symptoms were, on the whole, more favourable. The sickness was less troublesome and the wound was uniting well. The glass tube was washed out; there was only scanty discharge of bloody serum. The gauze was removed with some difficulty. It was firmly adherent and covered with healthy looking plastic lymph. All nourishment was given by the rectum. As there was slight abdominal distension and no flatus had passed we gave a saline purge in the evening, and the bowels were opened on the morning of Nov. 4th. The motions were darker in colour and partly formed. The sickness had now practically ceased, the patient's pulse and temperature were more satisfactory, and the chance of recovery seemed good. Nourishment was given by the mouth on Nov. 6th, and as more and more nutriment was taken by the natural channel the nutrient enemata were gradually lessened. On Nov. 7th a purulent discharge was observed from the tube for the first time. The discharge was sweet and quite devoid of bile. The tube was frequently filled with warm antiseptic lotion and aspirated. The wound, apart from the tube aperture, had now securely healed, and the bowels acted generally daily. All nourishment was now given by the mouth. The glass tube was removed and a rubber tube substituted. On Nov. 11th solid food was given for the first time. On Nov. 12th some severe pain was experienced of a colicky nature towards the right hypochondrium; this symptom persisted on the 13th. We were never able to explain it, and it passed away under subcutaneous injections of morphia. The tube, which had been gradually shortened, was entirely removed on Nov. 15th. About Nov. 17th the sinus had practically healed. The patient, who about this time was under the care of Dr. Weldon, got up on Nov. 24th, and went to Bournemouth on Dec. 18th wearing an abdominal belt. She is now well, but a small superficial sinus in connexion with a suture has lately been divided under nitrous oxide gas. A bacteriological examination was made of the pus by Dr. Slater of St. George's Hospital, and none of the ordinary organisms of suppuration were found, but antiseptics had been diligently used and might have modified the conditions really present. We regret that such an examination of the purulent contents of the gall-bladder was omitted amid the anxieties of a difficult operation.

In our remarks on this very interesting and important case we propose first to shortly review the literature of suppuration of the gall-bladder not dependent upon gallstones, and then we shall be in a better position to explain the probable nature of the case we have shortly narrated. We may at once say that suppurative cholecystitis apart from calculi is exceedingly rare. The English text-books except that of Murchison are silent on the possibility of suppuration of the gall-bladder occurring in connexion with typhoid fever. Osler¹ writes of "acute phlegmonous cholecystitis," and says "that it is a rare event; only seven instances of it have been recorded in the enormous statistics of Courvoisier. In a case which I

reported the patient died on the fifth day with symptoms of the most intense prostration, fever, and abdominal pain. Perforation may occur, with fatal peritonitis. Empyema of the gall-bladder is much more common, and in the great majority of cases is associated with gall-stones." Pepper² devotes a short article to inflammation of the gall-bladder and biliary ducts associated with pneumonia, typhoid and malarial fevers, and also in acute gastro-duodenitis from poisons and other causes. He mentions that when the cystic duct is obliterated and a suppurative cholecystitis present an empyema of the gall-bladder may burst and give rise to fatal peritonitis. He points out also that the patient may suffer from chills, recurring at irregular intervals and followed by sweating, the temperature being elevated to 103° and upwards. Murchison, in his well-known work on the continued fevers, alludes markedly to suppuration of the gall-bladder in association with typhoid fever. "The lining membrane of the gall-bladder," says this writer, "is very liable to become inflamed in enteric fever without producing any marked symptoms during life. Sometimes it is catarrhal, and the gall-bladder is proved to contain pus, as in the case related by Louis and in several which have occurred in my own practice." Murchison also refers to the diphtheritic form of inflammation as described by Rokitsky; and, lastly, he speaks definitely of the presence of ulcers in the mucous membrane of the gall-bladder, and refers to cases of this nature recorded by Andral, Jenner, and Trousseau. The same writer refers to a case which has many similarities to our own. A youth aged nineteen, in the London Fever Hospital, was seized with symptoms of peritonitis on the fifteenth day of enteric fever and died within twenty-six hours. The cause of the peritonitis was a perforating ulcer of the gall-bladder, which had allowed the bile to escape into the peritoneum. In connexion with this case reference is made to similar instances in the practice of Continental physicians and to a case of perforation of the gall-bladder in the practice of Dr. G. Kendal; but here gall-stones also existed. Drs. Gilbert and Girode, in the reports of the Biological Society of Paris for Saturday, Dec. 2nd, 1893, relate a case of purulent inflammation of the gall-bladder as a sequel of enteric fever. The pus, according to these authors, contained the "typhoid bacillus." The operation of cholecystotomy was performed five months subsequent to the typhoid attack, but the discovery of calculi throws doubt on the true nature of the case. Again, Gilbert and Dominici, writing in the reports of the Biological Society of Paris for Dec. 23rd, 1893, assert that they succeeded in producing suppuration in the gall-bladder and liver of rabbits by injecting a culture of the typhoid bacillus into the common duct. The gall-bladder was found thickened and full of pus, and foci of suppuration were scattered through the liver. Dr. Hale White, in vol. xiii. of the Pathological Society's Transactions, relates a case of fatal typhoid fever in a lad aged seventeen years. Characteristic ulcers were found in the liver and part of the ileum, and there was recent peritonitis round the gall-bladder, matting that organ and the lower edge of the liver to the intestines. The lymph was very soft, almost purulent. The gall-bladder was distended so that it measured 6½ in. in length and 3 in. across. Its walls were very thin, and in some places almost perforated. The bile which distended the gall-bladder appeared normal, and there was no obstruction to its flow. It will thus be seen that we have evidence to show that suppuration and ulceration of the gall-bladder do occur as a rare complication or sequel of typhoid fever.

As regards the case narrated by us, it is open to anyone to assert that it was not really enteric fever, but that the suppuration was due to some other cause, and the fever to septic absorption and pyæphlebitis. The diagnosis of typhoid fever was, however, at least as certain as is usually the case; the spleen was early felt to be enlarged, and the motions were characteristic. The bright yellow colour, sharply circumscribed margin, and vivid zone of hyperæmia which surrounded the ulcer were very suggestive of the enteric origin of the latter, and we are inclined to the belief that thus may be explained the nature of this remarkable case. Whatever was the exact origin of the ulcer it makes little difference to the surgical conduct of the case. We are inclined to lay stress upon the following points of interest in connexion with the surgical and after treatment. 1. The case affords an instance of the importance of abdominal

¹ Principles and Practice of Medicine.

² Text-book of the Theory and Practice of Medicine, vol. ii. p. 955.

section in grave and doubtful abdominal symptoms suggestive of perforation, and illustrates what may be accomplished by the aid of plenty of warm water and cleanliness. 2. The question of dealing with a sloughy perforated gall-bladder was the greatest point of importance and a matter of much embarrassment. Removal of the entire organ, with closure of the duct, was contemplated, but rejected on account of the time which had elapsed before the true nature of the case was recognised. We are inclined to lay great stress on the value of the gauze tampon in this case, and venture to express our belief that this valuable method hardly receives due recognition in cases where septic cavities communicate with the abdominal cavity. 3. The principle of drainage in a dependent position was also illustrated, and a posterior opening would probably be very advantageous in purulent collections between the stomach and the liver. The method of oblique puncture of the colon has already been alluded to by one of us in a debate at the Royal Medical and Chirurgical Society.³ 4. In the after treatment we need only allude to the rectal feeding, careful nursing, and the early opening of the bowels by saline purgatives.

Finally, we hope and believe that the condensed history of this case will be an important addition to the surgery of the gall-bladder, and we are of opinion that this is the first time that the operation of abdominal section has been successfully performed for so rare a condition as perforating ulcer of the gall-bladder not associated with calculous disease of that viscus.

COLITIS.

By W. HALE WHITE, M.D., F.R.C.P. LOND.,

PHYSICIAN TO GUY'S HOSPITAL.

Two correspondents¹ have recently written to THE LANCET asking for information on the subject of colitis. As I have seen several cases of it both during life and in the post-mortem room, and have recently collected a number from the post-mortem records of Guy's Hospital and various publications, I thought it might serve a useful purpose if I briefly drew attention to the chief varieties. Much fuller details will be given under the heading "Diseases of the Colon" in the "System of Medicine" about to be published under the editorship of Professor Allbutt. The colon is affected by a number of well understood diseases, as dysentery, tuberculosis, cancer, and anthrax, and in the post-mortem room many other extremely interesting conditions—as, for instance, follicular and distension ulcers and the forms of colitis associated with pyæmia, Bright's disease, &c.—are seen; but, apart from all these, there appear to be three forms of colitis of clinical interest, which may be termed "simple colitis," "membranous colitis," and "ulcerative colitis."

1. *Simple colitis*.—The chief symptom of this is diarrhoea. The motions contain much mucus and usually small, but sometimes large quantities of blood, which is fluid and but little altered, having clearly come from low down in the bowel. Under the microscope unaltered red blood cells, some leucocytes, and triple phosphate crystals may be seen. Early in the case there is usually very little faecal matter. The onset is generally sudden; the bowels may be open many times a day, and in most cases there is some abdominal pain (for the most part along the course of the colon), especially during defecation, but it is not often excruciating, nor is tenesmus very marked. Abdominal tenderness is nearly always present, chiefly over the sigmoid flexure, but it may be over the whole colon or the whole abdomen. The rectum may feel a little rough, and may be injected and covered with mucus; the tongue is covered with a white fur, but is commonly free at the edges and tip. If the case is severe the temperature is raised, and if the diarrhoea continues the patient loses weight. Flatulence, abdominal distension, loss of appetite, nausea, and vomiting may all be present, but are not commonly very striking. There is nothing noteworthy about the pulse, for its characters are the same as are usually observed in any severe abdominal disease. The cases vary much in severity, and if untreated may drag on for some time, even proving

fatal. The patients are often of a depressed, hypochondriacal turn of mind. The most important part of the treatment is to put the patient to bed, to keep him warm, and to give him only small quantities of milk at frequent intervals. Opium, bismuth, and compound catechu powder are valuable for checking the diarrhoea, but directly it appears that this is about to cease astringents should be withheld, for the subsequent constipation is often very troublesome. It is best overcome by rectal injections of glycerine or warm olive oil. The hæmorrhage is rarely severe enough to call for special treatment; probably injections of equal parts of water and liquor ferri perchloridi thrown as high up the rectum as possible are the best remedy. Milk or at the most farinaceous diet and complete rest in bed must be continued till all the symptoms have disappeared, and the longer the case has been left untreated the longer will the treatment last. If the patient die, the mucous membrane of the colon will be found to be injected, red, or even livid; the submucous tissue is swollen; an excess of mucus can be seen on the surface; and there may, in an exceptionally severe case, be a few flakes of lymph or a few minute quite superficial ulcers.

2. *Membranous colitis*.—In this disease the patient passes from the rectum whitish membranous casts of the bowel. The subjects of it are mostly women over twenty years of age; they are anæmic, thin, complain of feeling cold, and suffer much from indigestion, often accompanied by some constipation. They are poor eaters, and the tongue is slightly covered with a white fur. Usually they are of a depressed melancholy turn of mind, and appear to get very little enjoyment out of life. This description applies in a well-marked case to the habitual state of health, but from time to time there are exacerbations during which all these symptoms become more severe, and in addition there is much gripping pain in the abdomen, commonly in the course of the colon, and for the most part bearing no relation to food, and there may be nausea or even actual vomiting. After this state of things has gone on for a few days the patient begins to pass membranes and often blood from the bowel; this is not clotted, and has clearly come from low down. The membranes, which some patients call "skins" and others compare to pieces of tapeworm, are greyish or yellowish white, of sufficient consistency to remain intact when held up, and they vary from being very thin to about an eighth of an inch thick. A good specimen forms a complete cast of the colon, with perhaps some faecal matter in its interior, and may be more than a foot long; but often only shreds, which are clearly fragments of larger pieces, are present, and these may have been rolled up into a tight ball by the movements of the colon. Under the microscope the membranes are seen to be structureless and somewhat transparent, with, embedded in them, a few minute pieces of undigested food, faecal matter and some crystals, chiefly triple phosphate. Fatty epithelial cells may also be seen, clearly suggesting by their collection together and their arrangement that they are the cast-off cells of Lieberkühn's follicles; and the inner surface of the membrane is marked by a number of pits which correspond to the mouths of these follicles. Several leucocytes may also be seen. Chemically, these membranes are albuminous. The duration of an exacerbation during which membranes are passed may be only a few days, or they may continue to be passed for several years. Some motions contain faecal matter, blood, and membrane; others contain only one or two of these three constituents. The faecal matter is usually in the form of hard scybala, and constipation is more common than diarrhoea. I have seen one fatal case. No membranes had been passed for some time before death, and the colon was thin and marked with slight patches of congestion. Otherwise the whole body was normal. Treatment is very unsatisfactory. No drugs are known to have any certain effect for good. The body and mind must be maintained in the best general health possible. The patient should take plenty of outdoor exercise of such a nature as to occupy her mind as well as her body. Her diet should be abundant and simple, but at the same time carefully prepared, so as to tempt her to eat. Often the patient imagines she cannot eat this and that, and so she becomes very fastidious. A firm attempt to break this bad habit must be made. She should have some definite employment to occupy her mind, and when not at work should associate with cheerful companions rather than be left alone. Purgatives are particularly to be avoided. Every attempt must be made to get the bowels to act regularly, and the patient should go to the watercloset every morning whether or not she

¹ THE LANCET, Oct. 27th, 1894.

² THE LANCET, Dec. 15th, 1894, and Jan. 5th, 1895.

thinks the bowels will be moved. Her meals should be regular and she should go to bed early. If the pain or diarrhoea is at all severe she had better remain in bed, and some astringent—as bismuth—may be necessary. Opiates may be required for the pain, but they should be given sparingly, lest the patient become a confirmed opium or morphia taker, and all astringents should be ordered in small quantities because of the subsequent constipation. This is best overcome by a rectal injection of warm oil or glycerine. It has been suggested that in a very intractable case it might be justifiable to open the colon high up and, by allowing the feces for some time to pass out through the artificial anus, to give it rest, and at the same time to flush it from the artificial opening to the natural anus with boracic acid lotion.

3. *Ulcerative colitis*.—This disease is about equally common in the two sexes, and the sufferers from it are usually between twenty and fifty years of age. It is ushered in by frequent attacks of pain, usually paroxysmal, severe, griping, and referred to the front of the abdomen. Between the attacks, of which there may be several in a day, there may be a slight dull pain, or even none at all. Severe diarrhoea is another early and constant symptom, and the bowels may be open five or six or more times a day. The act of defecation is accompanied by much abdominal pain, but marked tenesmus is rare. The motions are fluid, slimy, and foul smelling; usually some fluid blood—it may even be a large quantity—is present, and a few small lumps of feces may be seen. Mucus is never present in large quantities. There may be some shred-like looking material, very like sloughs. For a day or two between the periods of diarrhoea there may be periods of constipation, during which more solid motions are passed. Many patients, before they have been admitted to the hospital, have suffered from vomiting, but this usually ceases under dieting and careful rest. The tongue is covered with a dirty whitish fur; as the disease progresses it becomes red and dry, with a brown fur. The patient has the pinched expression often seen in abdominal disease, he is extremely anæmic, his abdomen is somewhat distended, peristaltic movements may be visible, and ulceration may occasionally be felt per rectum. As the case goes on the anæmia and weakness progress, the patient looks extremely ill, and his pulse is feeble. Generally there is irregular pyrexia during the whole of an attack, the temperature commonly ranging between 100° and 102° F. The prognosis is extremely grave—in fact, we have no convincing evidence that the disease is recoverable. The duration is usually less than eight weeks; the commonest cause of death is exhaustion, but some patients succumb directly to perforation. In this country acute dysentery is so rare that there is not likely to be much confusion between it and ulcerative colitis. The different character of the stools and prominence of tenesmus, the burning pain within the anus, and the very frequent evacuation of the bowels in dysentery would help to establish the diagnosis. The diseases that I have known to be confounded with ulcerative colitis have been phthisis, malignant disease of the colon, intestinal obstruction, and pernicious anæmia. Post-mortem examination of many cases shows that in a typical example the muscular coat is exposed by ulceration, which is often so extensive that only islets of mucous membrane are left here and there. These are often considerably swollen, and consequently they look taller than they otherwise would, and frequently they are more or less sessile because of the ulceration that undermines them. The result is that a careless observer concludes that the colon is covered with polypi. The ulcers may be very numerous, and they may run together to form large, irregular ulcerated areas, with here and there perhaps a sloughy floor. The vessels are usually dilated; it is rare to see any attempt at healing. If the patient die early in the course of the disease the ulcers may be superficial and the mucous membrane very soft and congested. Sometimes the small intestine is affected as well as the colon, but to a less extent. Histologically the process is the same as is usually seen in chronic ulcerations. About half of the patients who die from ulcerative colitis show no disease except that of the intestine. The associated diseases which in any way suggest a special connexion are Bright's disease, gout, and hepatic abscess. Among twenty-three cases of ulcerative colitis of which I have notes of the condition of kidney, chronic interstitial nephritis was present in six, and of the remaining seventeen two had urate of soda in their joints. The association with suppuration of the liver is very rare, but probably there are two distinct varieties of it, as there are of hepatic abscesses in association with dysentery—

namely, the small multiple pyæmic abscess and the large solitary abscess. Treatment, unfortunately, appears to have very little effect on the disease. Absolute rest in bed, with slop diet and opium, and hot fomentations if the pain and diarrhoea are very severe, probably afford the best chance, but the prognosis is exceedingly grave. Several cases will be found recorded in the Guy's Hospital Reports² and one showing the association with hepatic abscess in THE LANCET.³

Harley-street, W.

A REVIEW OF ONE HUNDRED ABDOMINAL SECTIONS.¹

By GEORGE ELDER, M.D. GLASG.,

SURGEON TO THE SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

IT has seemed to me that the consideration of the results of my last 100 abdominal sections and comments would offer a sufficiently wide field for helpful criticism and discussion. They include all my operations of this class in the period from Feb. 23rd, 1893, to Nov. 17th, 1894, inclusive, and they are classified as follows:—

Operations.	No.	Results.	
		Recoveries.	Deaths.
Hysterectomy—			
Abdominal (for fibroids)	4	4	0
Vaginal (for cancer)	1	1	0
Ovariectomy—			
Single, 26	31	29	2
Double, 5			
Removal of the uterine appendages—			
(a) For inflammatory disease	33	32	1
(b) For uterine fibroids	4	4	0
(c) For tubal foetation (unruptured) ...	1	1	0
Cholecystotomy	5	5	0
Incision and drainage in tuberculous peritonitis	2	2	0
Incision and drainage of intra-peritoneal perityphilitic abscess	1	1	0
Incision and drainage of (?) pancreatic cyst	1	0	1
Intestinal obstruction	2	0	2
Resection of bowel	1	1	0
Exploratory incisions	14	13	1
Total	100	93	7

Looking at the list of deaths it will be seen that two followed ovariectomy. The first occurred in a woman aged sixty-four years—a patient of Dr. Carnelley of Ruddington—very stout and much troubled with chronic bronchitis; in fact, she was suffering from it on admission to the hospital. For several days treatment directed to alter this condition was tried unavailingly, and it was decided finally to perform the operation with the hope that the removal of the tumour-pressure would have a beneficial effect. Unfortunately, death took place four days subsequently from capillary bronchitis, there being no evidence of peritoneal inflammation. The second death took place ten days after a very simple double ovariectomy in an otherwise healthy woman forty years of age from an insidious and slowly advancing form of septic peritonitis rarely seen, and bearing a very striking resemblance in character to typhoid fever. This case certainly ought not to have died. One more favourable for operation could hardly be obtained, and during the progress of the case, and some time after, the manner of infection was to me a puzzle, until casually I learned that the medical man who assisted me had just before seen a case of scarlet fever. Possibly my ideas on this subject may be very extreme, but personally for years I have declined to attend contagious febrile maladies, solely on the ground that in operative procedures involving life the interests of the patient should be paramount. The third death followed in a married woman aged twenty-six years—a patient of Mr. John Hynes of Nottingham. For several years she had, both at home and in various hospitals, been treated for recurrent pelvic inflammation, undoubtedly due to leakage

² Vol. xlv.

³ THE LANCET, May 12th, 1894.

¹ A paper read at the Midland Branch of the British Medical Association, Grantham, on Nov. 29th, 1894.

from the pus tubes, until her health had become completely undermined. On abdominal section the tubes were found extensively and firmly adherent to intestine and broad ligaments, and their removal was a matter of extreme difficulty. Acute sepsis terminated the case forty-five hours after. Had I merely consulted my statistical record probably an examination of the difficulties of the case would have satisfied me, but the hopeless, dangerous condition into which the patient had drifted urged me to completely remove the diseased organs and give the woman the only chance she had of being restored to health. Whilst I think we ought not to operate on such cases too early—a mistake which can be nearly always avoided by a careful review of the history and symptoms of each case, assisted by a local examination—on the other hand, as is here well illustrated, the expectant treatment may be carried too far. The fourth fatality occurred in the person of an unmarried woman aged twenty-seven years, whom I first saw in consultation in June, 1893, with Mr. Walford of Stone Broom (to whom I am indebted for notes of the case, which I have to some extent used). This case is not only very unusual, but also instructive, and I may be pardoned in going somewhat into detail about it. The daughter of a publican, she had been credited for some time with pronounced alcoholic tendencies, and not, I think, without adequate grounds, although beyond occasional dyspeptic troubles her health had been good until Easter, 1893, when her fatal illness began. She then complained of pain on the left side of the abdomen, which suddenly took such an acute form on April 15th that Mr. Walford was sent for. The conditions then found were: distressing and foul vomiting, slight tenderness and resistance in the left iliac region, tongue clean and moist, pulse 150, thready, and temperature about 100° F. The bowels had acted the previous day, and the menstrual period was just over. The following are the notes taken at the time. "April 16th: Pain and sickness lessened. 19th: Temperature in the evening 102°; resistance in the left iliac region gone. 22nd to 23rd: A slight improvement in the general condition, yet there is constant abdominal pain now in the left hypochondriac region, accompanied by a 'distended feeling.' Is very restless, and sleep can only be obtained by narcotics. For fourteen days no properly formed motion was passed, but simply bile-stained mucus. Pulse rate lowered to 130 beats, irregular. Towards the end of this period a resistant mass, dull on percussion and tender, was noticed below the margin of the left ribs at a point about the junction of the hypochondriac and epigastric regions, and this slowly extended downwards to the right side. May 8th: As the patient was getting much worse Dr. Handford saw her in consultation, and thought the case possibly one of cystic tumour in the neighbourhood of the pancreas. May 16th: The tumour has kept steadily growing, especially towards the right side, its upper border being lost under the ribs; bulging is very noticeable. During the whole of the illness sickness had been almost constant, no natural sleep being obtained nor any proper evacuation of the bowels." The focal conditions at my visit were as follows: a prominent abdominal tumour could be seen and felt, extending from two inches and a half above the right nipple to within a hand's breadth of the iliac crest, only slightly encroaching upon the left hypochondr; dull to percussion, the dullness being continuous with that of the liver, and elastic. As it was obvious that an operation offered the patient her only chance, it was advised and carried out on June 8th. An incision being made above the most prominent part of the growth, and the peritoneal cavity opened, the stomach was found to be flattened out and adherent to the upper part of its surface; and, lower down, the omentum, much thickened with inflammatory exudate, adhered firmly to the parietal peritoneum and its inferior margin. On peeling this off the cyst lay exposed intimately connected with the colon and deeper parts, so that its precise origin could not be made out, nor was it deemed advisable to attempt its enucleation. From four to five pints of greenish-black or brownish liquid containing a few flocculi were removed by aspiration, and the cyst opening after irrigation was stitched to the parietes and a drainage-tube inserted. As some of the fluid had got into the peritoneal cavity a second (glass) tube was left in Douglas's pouch. The patient rallied well from the operation and seemed to be going on favourably until eighteen hours later, when suddenly she became cold, pulseless, and gasping for breath, dying in a few minutes. No necropsy was allowed, but, looking back at the history of her

eight weeks' illness from the light thrown upon the case by the operation, there seems to be little doubt but that it was an example of pancreatic cyst. The fifth and sixth deaths occurred after operations for the relief of intestinal obstruction. The first was that of a woman aged thirty-two years, who had been in ill-health since a miscarriage two years and a half before, and had gone to Matlock for change. Her chief symptoms had been frequently recurring attacks of "spasms" and obstinate constipation. On the evening of her arrival, after a journey of 130 miles, she was suddenly seized with abdominal pains, and early next morning Mr. Moxon was called in, and was able by hot applications and hypodermic injections of morphia to control the symptoms. Neither now nor subsequently was the vomit feculent. On the following day evidence of general peritonitis showed itself, and when I saw her with Mr. Moxon on the fourth day the abdomen was uniformly distended, tympanitic, and slightly tender, particularly high up on the left side. No cause of the trouble could be made out, although a careful examination of the usual seats of hernia, pelvic organs, and the lower bowel was made, and as it was evident that the patient's condition was becoming more serious, an operation was advised, and done on the following morning. On opening the peritoneal cavity a considerable quantity of serous fluid welled out, and it was noted how intensely congested the presenting parts were, especially about the cæcum and vermiform appendix, the latter, although somewhat thickened, being quite intact and containing no concretion. Neither by manipulation of the abdominal contents whilst *in situ* nor by touch could anything beyond the peritonitis be discovered, so it was decided to close the wound in the usual manner, providing for drainage. For three days the patient lived—neither the better nor the worse, in my opinion—for the operation. The distension day by day slightly increased, mainly in the upper half of the abdomen, although several times flatus was passed in large quantities after turpentine enemata; but, do what we would, no satisfactory evacuation of the bowels could be obtained. The other case of intestinal obstruction was due to volvulus of the large bowel in a boy aged seventeen years, whom I saw five days after the seizure with Mr. Howson of Snelton. He then had general peritonitis, and on opening the abdominal cavity the twisted portion quickly came into view, and was without difficulty rectified. The bowel was intensely congested, showing here and there patches of reddish-black discolouration; but in the hope that it would recover itself the bowel was returned, and the operation finished in the usual way. It would probably have been better surgery to have either made an artificial anus or attached the damaged bowel to the parietes and waited for further developments, but the result in this case, probably, would have been the same, as the boy never thoroughly recovered from the shock and died some nine hours afterwards. As is well known, such cases as the above are not very hopeful subjects for operation, partly owing to the uncertainty of their initial lesion, and also to the lateness as a rule at which surgical aid is called in. What the starting-point in the first case was it is impossible now to say, but it seems to me not unlikely that there was a slowly invading stricture of the small bowel which suddenly became occluded. This would account not only for the long illness the patient previously had, in which "spasms" and obstinate constipation were prominent symptoms, but also for the sequent train of events. The second case, as was to be expected from its nature, ran a more acute course. The last death in the series was operated upon by me in conjunction with Mr. A. E. Lyster of Long Eaton. The woman, aged forty years, had been bedridden for months with a pelvic growth, which when I saw her was accompanied by a large amount of ascites. Although there could be little doubt about the malignancy of the case the friends were anxious that an exploratory incision should be made, which was done, confirming our diagnosis. The woman died a few days afterwards, and the worst that the operation did for her was merely to antedate the events by a few days.

Singularly enough, six deaths happened in the first fifteen cases, so that there has only been one in the last eighty-five, viz., that occurring on March 13th this year, after the operation for volvulus. Amongst the thirty-one ovarian cystomata there were one dermoid, two papillomata (one suppurating), and two with twisted pedicles. As to age, three patients were sixty-four and one sixty-five years, one of the former, a patient of Dr. Macdonald of Crich, having a somewhat rare experience, inasmuch as she had removed by me

a large right multilobular tumour, and twelve years before Dr. Granville Bantock, at the Samaritan Hospital, London, removed one from the other side.

One of the most instructive cases of the series was that of a woman aged forty years, an inmate of the Belper Workhouse, sent to me by Mr. Allen. She had been tapped fourteen times for ascites, the last within a fortnight of her admission into hospital last April. So quickly had reaccumulation taken place that then her abdomen was much distended, and through the fluid could be felt, at the lower third of the abdomen, a fixed resistant mass, which per vaginam could be felt filling up the pelvic cavity. It was decided to open the abdomen, when the papillomatous nature of the growth revealed itself; and at first, on account of its adhesions, it was thought to be quite impossible to enucleate it, but ultimately this was done and an elastic ligature thrown round its base to control the very free hæmorrhage. The growth was then cut off, when it was found that what had seemed one homogeneous mass was in reality two growths springing from both ovaries which had met in the middle and overlapped the uterus. The stump was therefore disinfected, as in an ordinary hysterectomy, and treated extra-peritoneally, with the result that the patient made a very good recovery and has remained in perfect health ever since.* In treating the pedicle in the four supra-vaginal hysterectomies for fibroids the intra-peritoneal method was used in one case, and tying off the arterial supply and fixing the stump to the parietes, or what is known as the "mixed method," in the other three.

In the matter of the removal of the uterine appendages for inflammatory disease no operation was performed without ample justification in the clinical symptoms and local conditions of the case, supplemented, when necessary, by an examination under an anæsthetic, and also acquainting those concerned with the immediate and remote effects of the operation. Now one word as to the place of exploratory incisions in this branch of surgery. No hard-and-fast line can be laid down in this matter, inasmuch as what would be rash because dangerous in the hands of one surgeon is in the hands of another a safe and reasonable evolution of diagnostic methods. In saying this I am far from wishing to underrate the gravity of the procedure, but, whilst granting this, it seems to me that when we have exhausted all other available aids to diagnosis, and either completely or in some material point failed, or when with a full knowledge of the pathology of the case there is a doubt as to its operable character, then we are perfectly justified, after stating the nature and limits of the proposed operation, in counselling those concerned to run the very slight risk which is involved. I need hardly say that at such a time one ought to be prepared to undertake whatever operation the exigencies of the case demands, so that no one should perform an exploratory operation without being perfectly familiar with the technique of abdominal surgery.

Nottingham.

ON CYCLING AS A CAUSE OF HEART DISEASE.

By GEORGE HERSCHELL, M.D. LOND.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, SOHO SQUARE.

An Abstract of a Paper communicated to the Eighth International Congress of Hygiene and Demography, Budapest, 1894.

THE chief danger of cycling, or rather the reason why it may become more injurious than some other forms of exercise, is the fact that a cyclist takes much more exercise than he is aware of, and is very frequently tempted to overtax his powers. He starts off in the morning for a ride fresh and vigorous, having previously mapped out his course; but when the time arrives for his midday meal he may have some few miles yet to go. He has perhaps over-rated his capacity; or the condition of the roads renders it impossible to travel at the rate upon which he had based his calculations. But he is hungry, and so he redoubles his efforts to reach his destination and when he arrives there he is utterly fagged out and has lost his appetite. As an example of the facility

with which one may be led into taking more exertion than one has counted upon I may relate a case which came under my notice a few weeks ago. A gentleman who had not ridden for some time started out one morning for a run into the country, neglecting to take any lamp. When he arrived at his destination it came on to rain, and the friends whom he was visiting prevailed upon him to stay until late in the evening. At half-past seven he found himself still fifteen miles from home, and on that particular evening police regulations compelled the lamps to be lighted at a quarter past eight. It was now a race against time, but he succeeded in reaching home only a few minutes after that hour. I saw him at nine o'clock. His pulse was then 125, and he complained of thirst, restlessness, and a feeling of oppression at the chest. At 9.15 his pulse was 120. At ten it was 110. At eleven o'clock it had sunk to 100. He then retired to bed, but passed a sleepless night. On rising in the morning his pulse was 90, and it did not reach the normal 68 until the day after. The commonest way, however, in which the cyclist injures himself is in climbing hills. He is nearing the top of the hill, and the heart is dilated with the strain put upon it by the increased arterial tension. If the rider were now to stop and recover himself no harm would be done. But in too many cases he sees that only a few more revolutions of the wheel will be required to carry him to the top. So he redoubles his exertions, putting further strain upon a heart already taxed to the utmost limit of its capacity, and in those few moments damage has been done to the heart from which it perhaps cannot recover.

I believe that it is usual at the commencement of a club run for the riders to agree that they will adapt their pace to the slowest member. That is all very well in theory, but what really takes place is that after a time one of the faster riders unconsciously quickens his pace. The rest of the club follow suit, and before very long they are all travelling at a rate which is far beyond the capacity of a certain proportion of the set. To be unable to keep up with the rest of the club is a confession of effeminacy, and it would be morally impossible to get off your machine and walk up a hill which your friends are riding up. Another circumstance which increases the deadliness of the modern cycle is the fact that it is nowadays considered a point of honour, especially among novices, to ride with as high a gear as possible. It is, I am sure, no exaggeration to say that 90 per cent. of all riders are using a gear much too high for their strength. For the benefit of those who are not practical cyclists I will here explain what is meant by "gear." In the early days of cycling the pedals were attached directly to the axis of the driving wheel. The effect of this was that the largest wheel which could be used was determined by the length of the legs of the rider. And since the distance which a machine would travel with one revolution of the pedals depended upon the size of the wheel, tall men were at a great advantage over short ones when it came to racing. So every one rode as large a wheel as he could, and strictured urethra from perineal pressure was common. The introduction of geared machines altered all this. The pedals, instead of being attached to the hub of the driving wheel, communicate motion to a cog-wheel, and this in its turn, by means of a chain or other mechanical device, rotates another wheel rigidly fastened to the hub of the driving wheel. By varying the sizes of the respective wheels the driving wheel can be caused to rotate a greater number of times than the pedals. If, therefore, a driving wheel of thirty inches in diameter were caused to rotate twice for every once that the pedals went round, you would be securing all the advantage of a sixty-inch wheel as regards speed with half the weight. Of course the more a machine is geared up the harder work it is to push it. That is what is meant by a high gear. Machines for racing are geared up to seventy inches or more. Boys of fifteen or sixteen years of age boast that they ride machines geared up to sixty-three inches, whereas a fifty-six inch gear would be much more suitable for them.

The subject-matter of this paper is intended to apply to the thousands of every-day cyclists. I am not taking into consideration the path and road racers. These men are deliberately sacrificing their future health for the sake of winning a few prizes. What shall we say to 460 miles ridden in twenty-four hours at Herne Hill last year? At this race some of the men rode until they dropped off their machines. Another very reprehensible thing is what is known as a "hill-climbing contest." Everything that I have said with regard to riding up hills applies here with double force. Hills of the steepest gradient are purposely

* Feb. 26th, 1895: This patient still keeps well, having had no recurrence.

selected, and the competitors ride up them against time, trying to break existing records for that particular hill. Nothing more suicidal or more certain to produce heart disease can possibly be imagined.

The effects upon the heart of the strain of excessive cycling may be divided into four groups:—1. Simple hypertrophy of the heart. 2. Acute dilatation of the heart, ending either in recovery if the cause be removed or in death if it persists. 3. Chronic valvular disease of the heart. 4. Functional derangement of the heart.

GROUP 1.—SIMPLE HYPERTROPHY OF THE HEART.

This is apt to occur in well-trained riders who do a great deal of cycling, and may be looked upon as a compensatory effort of nature to enable the work to be performed. Cycling for extended periods of time at a great pace, like other forms of prolonged muscular exertion, enormously increases the blood pressure in the arteries. Hypertrophy of the heart follows the law which governs all muscles—that increased work is followed by increased growth if the nutrition is kept up. Moderate degrees of hypertrophy are quite compatible with health, and are usually unattended with symptoms. The danger, however, is in the ultimate effects which are liable to ensue. The heightened blood pressure in the arteries gradually produces a hard inelastic condition of their walls, which perpetuates and increases the hypertrophy. Moreover, these altered arteries are prone sooner or later to undergo degenerative changes, and, having lost their normal elasticity, to give way on some occasion of sudden strain. As a rule, the athlete enjoys vigorous health for the few years during which he is actively working, and his heart is only enlarged enough to meet the constant demands upon it; but when the cyclist, no longer in his first youth and unable to compete with younger men, relaxes his efforts, his heart is now too large for the work it is required to do, and the symptoms of hypertrophy soon make themselves felt. Hypertrophy following over-exertion may disappear under proper treatment if taken early and the cause removed, but when it has persisted for a number of years this is rarely, if ever, possible, and ulterior changes are apt to ensue. It is well known that athletes are liable to rapid deterioration of health when they relinquish their active exercises. It is also probable that a hypertrophied heart may undergo degenerative changes whilst in active daily work. This is rendered probable by what is known to happen in the case of flic-cutters, whose work consists in quickly flexing their biceps. The effect of this is to cause hypertrophy of that muscle, but after a few years it atrophies. This is so certainly known in the trade that flic-cutters receive very high wages, based upon the probable working life of their hypertrophied biceps. It is possible that in this way we may have an explanation of the well-known fact that compensatory hypertrophy of the heart cannot be preserved indefinitely, although the valve lesion may be stationary. Hypertrophy of the heart produced by cycling may terminate in one of these ways: (1) recovery; (2) valvular disease and disease of the aorta; (3) degeneration of the heart muscle.

GROUP 2.—ACUTE DILATATION OF THE HEART.

Until the individual first shows signs of being "out of breath" both ventricles are sending equal quantities of blood into the pulmonic and aortic systems respectively in equal periods of time. At each beat the left heart is withdrawing from the lungs exactly the same quantity of blood that has been forced into them by the right heart. And it is evident that the oxygen supplied to the blood is exactly equal to what the body requires. Respiration and the heart's action, although hurried by the exercise, are carried on normally and without unpleasant sensations. If, however, the exercise be continued, the heart is stimulated to contract at such a rate that the respiratory muscles cannot keep pace with it. Besides, the time during which it is possible for the blood to come into contact with the oxygen in the lungs is shortened. "Shortness of breath" is thus produced, the sensation being, as we all know, the cry of the blood for more oxygen. Accompanying this will be obstruction to the circulation through the lungs, and a small abnormal amount of residual blood will remain in the right ventricle. If the extreme muscular efforts are continued the excess of venous blood in the pulmonary vessels will increase with every beat and the right heart will rapidly dilate. At this stage the quantities of blood thrown out from the two ventricles are unequal. The heart continues beating and expelling the whole of its contents with the exception of the residual blood in the right ventricle. At last a moment comes when

from fatigue the muscles at the base of the ventricles are no longer able to adapt the ring to which the bases of the valves are attached so that the valves will efficiently close them. And since the whole of the valvular ring is expanded while the valves have retained their former size regurgitation must take place. If at this point the individual ceases his muscular efforts, in all probability the heart will quickly recover itself; but if the recovery is not complete there may remain permanent incompetence of the tricuspid valve. On the other hand, if the exertion is kept up, the heart, being unable to pass on the whole quantity of blood that reaches it at each beat, undergoes rapid dilatation of the right ventricle and death by *asthete* is the result. Of such a character doubtless are the cases of sudden heart failure which has occasionally caused the death of riders even in the course of a journey. The following fatal case of acute overstraining of the heart occasioned by cycling came under my notice in 1884, and the notes may be of interest as showing the symptoms which may be expected. A man aged forty-six years had lately taken to cycling and used a heavy tricycle. After having followed the sport for three weeks and made some short journeys he attempted to ride from Brighton, where he resided, to London, a distance of fifty-three miles. I was called to see him about seven o'clock in the evening at his hotel and found him cyanosed and very exhausted. There was intense dyspnoea, and his pulse was 144 per minute and very feeble. His heart's action was irregular and weak. Dulness extended transversely from a quarter of an inch outside the right parasternal line to the left mammary line. The apex was beating in the sixth intercostal space in the left mammary line. A systolic bruit was apparent both over the mitral and tricuspid areas, and there was pulsation in the veins of the neck. The urine contained a trace of albumen. Unfortunately, in spite of treatment, he gradually sank, and died early next morning. I was informed that the patient had never previously exhibited any symptoms which pointed to heart disease. The absence of marked hypertrophy of the heart would also negative the supposition. No post-mortem examination could be obtained. The case was evidently one of acute dilatation of the heart in a man not so young as to be able to undertake with impunity such a muscular task as a ride of fifty-three miles against time. The overstrained and distended heart was unable to contract vigorously enough to restore the equilibrium, and fatal syncope was the result. Acute dilatation of the heart produced by cycling, then, may terminate either—(1) in recovery; or (2) in the production of valvular disease.

GROUP 3.—CHRONIC VALVULAR DISEASE OF THE HEART.

I believe that the mechanism by which permanent valvular disease of the heart is produced by overstrain from exercises such as cycling is twofold: 1. As a sequel to acute dilatation of the heart. The ring to which the bases of the auriculo-ventricular valves are attached having been once stretched sufficiently to allow regurgitation to take place does not recover itself, but remains permanently enlarged. We shall thus have regurgitation into the auricle. The case will then pass through the usual stages of compensatory hypertrophy, with probably final breaking down of compensation. 2. As a result of hypertrophy. It is probable that the constant high tension in the arterial system with the resulting strain upon the valves occasions slight injuries to their surface with the subsequent production of sclerotic changes. In cases which have come under my notice I have found that the great majority suffered from lesions of the aortic valves, and I have reason to believe that the hypertrophy always ante-dated the valve mischief. This is only what we might expect. The aorta, unlike the heart, cannot strengthen itself against an excessive strain, as its activity is practically nothing more than the recoil of elastic tissue. Strain of such a structure will cause chronic endarteritis and loss of elasticity. If you examine such an artery with a microscope you will find small points of endarteritis upon the inner coat and patches of diffuse granular exudation in the middle one. The next step will be dilatation or pouching of the aorta just above the valves which are as yet competent. Many cases come under observation in this condition, and the following may be taken as a typical example. A man thirty-one years of age attended my out-patient department at the hospital in the autumn of 1892. He complained of palpitation and shortness of breath. During the summer he had been constantly riding the bicycle, going on an average sixty miles a day for three days a week. On examination there was evident hypertrophy of the heart, the apex beating

in the anterior axillary line. The right margin of cardiac dulness was half an inch to the right of the sternum. The arterial dulness over the upper edges of the sternum was decidedly wider than it should be, pointing to dilatation of the aorta. There were no bruits and no thrills, but there was marked accentuation of the aortic second sound. This would probably be the first stage in the production of valvular disease. As regards the further course of such a case we have three possibilities: (1) the aortic ring may be stretched by the pouching of the aorta and regurgitation may take place; (2) a valve may actually give way; (3) sclerotic changes may take place in the valves. In any of these cases the disease will follow the usual course of valvular mischief produced by other causes.

GROUP 4.—FUNCTIONAL DERANGEMENT OF THE HEART.

I believe that this condition as the result of cycling is much more common than is generally supposed. Many cases are but slight and quickly recover, so that they are overlooked or ascribed to other causes. Da Costa applied the term "irritable heart" to chronic cases of tachycardia which he observed amongst the men engaged in the American Civil War. This condition resembled in many respects the functional affections of the heart which we see as the result of strain when cycling. It is extremely probable that they are identical as regards pathology. I believe that these conditions always follow a temporary dilatation of the heart in the following manner. As we have shown, right-sided dilatation of the heart is invariably produced by the prolonged strain of too rapid cycling. This dilatation having subsided when the cause has ceased to operate, the heart remains irritable from the stretching that its muscular fibres have undergone. It would seem in these cases almost as if the inhibitory function of the pneumogastric nerve were suspended, for when the heart has so far recovered itself from the immediate effects of the strain that the pulse-rate has fallen to normal any slight exertion or emotion will bring the palpitation on again. The symptoms which I have observed in these cases have been chiefly the following.

Palpitation of the heart.—This is very distressing, and usually occurs on the slightest exertion or emotion. If not relieved by appropriate treatment it may possibly end in the permanent establishment of a "rapid heart." Dr. Bristowe has narrated a case in which paroxysms of extreme rapidity of the heart's action were probably initiated in a boy eight years of age from physical exertion in a paper chase. This ultimately became a case of confirmed "rapid heart," and ended in sudden death at the age of nineteen years.

Shortness of breath.—This usually accompanies the palpitation and comes on when the patient exerts himself even in a slight degree.

Sensation of sinking at the epigastrium.—In certain of my cases this has been one of the most prominent symptoms.

Subjective sensations in the region of the heart.—The patient is conscious of the heart's action, and often feels as if it were going to stop.

Intermittency of the heart's action.—I believe that I have traced the origin of this condition in several cases to a temporary dilatation of the heart as the result of hill-climbing.

Anginoid symptoms.—Two of my cases complained chiefly of pain in the cardiac region, coming on in paroxysms, running down the left arm, and accompanied by a sense of suffocation and impending death. They both completely recovered under appropriate treatment.

These, then, are some of the possible evils of excessive cycling. On the other hand, we have the undoubted fact that in moderation and under proper conditions it is one of the most health-giving forms of exercise. In established heart disease, strange as it may seem, it is one of our most potent remedial measures. Commencing with the lowest gearing for the shortest periods and along level roads, carefully graduated cycling is able to establish that compensatory hypertrophy which alone can enable the victims of valvular disease of the heart to live in comfort and usefulness. For this purpose I prescribe it largely.

Let us now turn to preventive measures and consider some precautions against the dangers of this fascinating sport. I would lay stress upon the following points:—

1. *The use of a low gear.*—This has been already described.

2. *The upright position in riding.*—The stooping posture, so habitual to the modern cyclist, by contracting the chest prevents the proper expansion of the lungs, and by interfering

with the aeration of the blood causes the condition of breathlessness to come on quicker.

3. *Adequate food when riding, and the avoidance of muscle poisons such as beef-tea.*—A badly nourished muscle gives way sooner than one which is well fed. As I have pointed out in a previous paper, it is probable that the digestive power of the stomach is inhibited during riding. From this it follows that the ordinary food taken by the cyclist on the track or road is not digested, and does not provide him with energy. In the paper alluded to I advocated the use of peptonised gruel or soup.

4. *The cyclist must avoid preparations of kola and coca.*—These by numbing the sense of weariness enable injuriously excessive work to be done almost without the knowledge of the rider.

5. *On no account should the cyclist continue riding after he has commenced to feel short of breath, or when there is the slightest sensation of uneasiness in the chest.*—This simple precaution is one which cannot be too earnestly recommended.

Queen Anne-street, W.

SUCCESSFUL OVARIOTOMY ON A PATIENT IN HER EIGHTY-SEVENTH YEAR

UPON WHOM OVARIOTOMY HAD ALSO BEEN PERFORMED WHEN SHE WAS NEARLY EIGHTY YEARS OF AGE.

By E. MATTHEWS OWENS, L.R.C.P. EDIN.,
M.R.C.S. ENG.

MANY of the readers of THE LANCET who are interested in gynecological matters will perhaps remember that a case was recorded by Mr. Lawson Tait at a meeting of the Gynecological Society in 1888 of a patient seventy-nine years and ten months who had been successfully operated upon by me for a large parovarian cyst by abdominal section. The case remained for some time as the oldest on record; but as time went on it was exceeded. Dr. Herbert Spencer¹ records one in a patient eighty-two years and two months old. Also there is one by Mr. Bush² in a patient in her eighty-fifth year. But any case in a patient over eighty years of age must still be considered as worth recording; otherwise Dr. Heywood Smith would not publish one in a patient eighty-one years of age.³ Hence it is that I feel rather proud in being able to put on record a successful ovariectomy in a patient in her eighty-seventh year.

A married woman who had been operated upon by me in December, 1887, being then aged seventy-nine years and ten months, remained quite well until the middle of 1893, when she noticed that her abdomen was swelling. It gradually increased until it prevented her from taking exercise. I was asked to see her in February, 1894, and diagnosed a fibro-cystic tumour of the ovary, evidently growing rapidly. From the history given me I am afraid I rather ridiculed any operative interference; but not so the patient, for when she distinctly understood that it was an ovarian tumour she called her family together, they acting as jury and she as judge, and the verdict being "that as her life had become a burden through the size of the tumour, and she had survived one operation, therefore she saw no reason why she should not survive a second." I was sent for, told the decision, and requested to operate as soon as possible, she and her friends accepting all responsibility. Under the circumstances I thought it well not to lose any time, so three days after the decision was arrived at—viz., on May 3rd, 1894 (that is, six years and three months since she had been previously operated upon, her age being thus exactly eighty-six years and one month)—I operated at her own house, Dr. Lillian Cooper giving chloroform. The operation was quite simple, but as in 1887 the parovarian cyst had been removed from the left side it was a fair deduction to make that the present tumour would arise from the right side. Therefore I made my incision to the right side of the 1887 one, but on opening the peritoneum I had to my astonishment to get over to the left side to reach the pedicle of the tumour, which proved to be, as diagnosed, fibro-cystic. The patient made an excellent recovery, without a bad symptom as

¹ Brit. Med. Jour., Dec. 9th, 1893.

² Ibid., July 14th, 1894.

³ THE LANCET, June 30th, 1894.

regards the operation, but some cystitis appeared, caused, I think, by over-anxiety of the nurse, who in order to make sure of destroying all septic germs soaked the catheter in too strong a solution of carbolic acid, which so softened the instrument that, I think, some bits of its covering were left adhering to the mucous membrane of the bladder. Perhaps also the mode of feeding aggravated matters; but I dared not and did not alter it, and with suitable treatment all cystitis gradually subsided. I need hardly say that it was not a case in which to rigidly adhere to gruel and sips of tepid or iced water. Instead, directly the operation was over, I commenced with nutrient enemata every two or three hours, and after twelve hours prepared essence of beef, brandy, zymised milk, &c., were given by mouth. Until she was convalescent I am afraid to say how much brandy, coca wine, and essence of beef she consumed; but it was a very large quantity. On one thing I was determined—namely, that if she died it should not be from exhaustion. There is also another part of treatment that was carried out in this case which I think I may pronounce as being of immense benefit—viz., hypodermic injections of sulphuric ether, not only during the operation, but also during convalescence. The nurse's instructions were to give the injections whenever she thought that the patient looked, or expressed herself as feeling, exhausted, even if she had had stimulants by the mouth only a short time previously. Exhaustion was to mean hypodermic injection at once. I must say that this treatment acted splendidly. She is now (Aug. 24th, 1894) in most robust health, driving, and walking, and looks as if she would live to be a hundred years of age.

Remarks.—The interest of this case lies not only in the extreme age of the patient, but also in that it clears up a doubtful fact, for it is proved to be quite possible to have a parovarian cyst removed and subsequently for a true ovarian cyst to be developed on the same side; and this opens up an important point—viz., whether it is good surgery to simply shell out a parovarian cyst, leaving the appendages, or whether it is not better to remove everything on that side. Had I done this in 1887 I should not now be in the position, for the time being, of holding the honour of having performed successful ovariectomy in a patient of the most advanced age.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CURIOUS CASE OF CARBOLIC ACID POISONING.

By W. H. BROWN, F.R.C.S. IREL.

A FEW days ago I was asked to see, in consultation with a medical man, a child three years of age. An hour prior to my visit an attendant had been directed to clean the child's head with carbolic oil. After she had been rubbing it for three minutes she discovered that in place of carbolic oil she had used pure carbolic acid. So soon as the mistake was noticed the head was promptly washed, but within five minutes the child lost consciousness. When an hour later I saw the child it was deeply comatose, in which condition it remained for five hours, when two ounces of olive-green-coloured urine were passed. The return to consciousness was very gradual, the child having for several hours a dazed appearance. At the end of three days the urine became normal, and the albumen, of which there had been a trace, disappeared. Seeing the frequency with which carbolic acid is used, I thought it right to mention this instance of its rapid absorption by the unbroken skin.

Leeds.

CALCULUS PASSED BY THE FEMALE URETHRA.

By J. GORDON SHARP, M.B., C.M. EDIN.,

LATE RESEARCH STUDENT IN PHARMACOLOGY, OWENS COLLEGE, VICTORIA UNIVERSITY, MANCHESTER.

SUBSEQUENTLY to attacks of renal colic a woman between forty and fifty years of age passes calculi of a rich puce colour. The pigment is due to an organic compound of iron,

and an account of their physiological chemistry has been published by me.¹ Hitherto the stones passed have been small, with a few large ones weighing from five to six grains; but recently the woman passed a stone the length of which is $\frac{3}{4}$ in., and the circumference at the greatest part is $\frac{1}{2}$ in. The weight is exactly ten grains. Like all the others passed, this calculus is intensely hard, and it is highly polished and smooth. The wonder is that such a large stone could be passed with so little constitutional disturbance, for after she has had an attack of colic she enjoys fairly good health. For some three years the patient has, at intervals of four or five months, or occasionally longer, passed a number of stones of the character indicated, and, although none of them have been so large in circumference as the one described, still they are sufficiently large to occasion some surprise that they should have been voided with comparatively so little trouble.

Leeds.

AN UNUSUAL FORM OF HYMEN.

By C. E. PURSLOW, M.D. LOND.,

HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL; ASSISTANT TO THE CHAIRS OF MIDWIFERY AND GYNECOLOGY, MASON COLLEGE, BIRMINGHAM.

THE patient, aged fifty-seven, unmarried, was admitted to the Queen's Hospital, Birmingham, on Jan. 3rd, 1895. Menstruation had never ceased, and as the hymen would not admit the finger it was considered advisable to examine thoroughly under chloroform. When she was anaesthetised it was seen that the hymen presented two separate, small rounded apertures, each just admitting the uterine sound. The finger was passed forcibly, and two small polyp were found to be protruding through the cervix; these were removed. The point of interest about the case is that the hymen approached to that variety described in the text-books as cribriform, and although almost all the text-books agree in stating that such a form of hymen may be found recent investigators have denied that any such condition of hymen ever does exist.

ST. GEORGE'S HOSPITAL.

AN EXCEPTIONAL CASE OF EPITHELIOMA OF THE TONGUE
IN A WOMAN; REMOVAL; RECURRENCE;
DEATH IN TEN MONTHS.

(Under the care of Mr. WARRINGTON HAWARD.)

ALTHOUGH epithelioma of the tongue rarely attacks females, occasional cases such as the following remind us that they are not quite exempt from it and that it does sometimes occur in them; according to Mr. A. E. Barker this is in the proportion of 247 males to 46 females. This is probably above the average for true cancers. From the statistical reports of St. Thomas's Hospital for the years 1861-93 inclusive we learn that there were 160 cases of epithelioma of the tongue under treatment, of which number only sixteen patients were women. Cancer of any part of the body is rare at the age of this patient; it sometimes commences in the cervix uteri at even an earlier date, but is scarcely ever seen in the tongue. Gurli, who collected statistics of 11,131 cases of cancer, found that in 4789 in which the age of the patients was recorded, only 0.4 per cent. recovered under the age of twenty. We are inclined to the opinion that when epithelioma affects the tongue in women a larger proportion of the cases will be found to be under the age of thirty than obtains in the other sex. This case

¹ Journal of Anatomy and Physiology, July, 1894.

illustrates the statement in one of our text-books on surgery very vividly: "The age of the patient exerts a considerable influence on the growth and malignancy of the tumour. As a rule, the younger the patient the more rapidly does the tumour grow, the earlier does it affect the lymphatic glands, and the more widely disseminated are the secondary growths." For the notes of this case we are indebted to Mr. Arthur H. Ward, surgical registrar.

The patient was admitted into St. George's Hospital on Jan. 5th, 1894, under the care of Mr. Warrington Haward. She was a healthy looking woman, aged twenty-three years, with no history of tubercle or syphilis. Six weeks before admission she noticed a slight soreness and swelling on the right margin of the tongue. Carious molar stumps were removed from the right lower jaw about four weeks later. She had worn a tooth-plate on the upper jaw for two years. On her admission there was found to be an oval infiltrated area of the size of a shilling, which was situated far back on the right margin of the tongue. The surface was whitish, irregular, and raised. No glands could be felt in the submaxillary region. The dorsum of the tongue was normal. No signs of syphilis or tubercle were present. Carious stumps were removed from the right upper jaw, and iodide of potassium was given in ten-grain doses three times a day. Calomel was applied locally. A fortnight later a nodule the size of a split pea was found on the dorsum of the tongue, about half an inch from the original ulcer. A consultation was held, and the growth diagnosed as epithelioma. A small portion was removed and microscopically examined; it was a squamous-celled epithelioma. The right half of the tongue was then removed by the *chaine écarée*. In a fortnight an enlarged gland was felt near the angle of the jaw. The patient was sent to the convalescent hospital at Wimbledon for three weeks and then went home to the country. The cervical glands were then enlarging. Dr. Livingston reported that the growth recurred both in the scar and in the right tonsil. The mouth could not be opened. The cervical glands suppurated, and the patient became very anæmic. She died exhausted ten months after the operation, and just over a year since the first appearance of the disease.

SUSSEX COUNTY HOSPITAL.

A CASE OF PERFORATED GASTRIC ULCER TREATED BY LAPAROTOMY; RECOVERY; REMARKS.

(Under the care of Mr. R. F. JOWERS.)

We give with the account of his successful treatment of perforation of a gastric ulcer a table contributed by Mr. Jowers of published cases of operation for similar perforations, which will be useful for reference. There were several circumstances in his favour, as is pointed out by him in his remarks, but without the promptitude and skill in overcoming difficulties inherent in the case which the surgeon manifested a fatal termination must have ensued. In a paper recently read before the British Medical Association Mr. Gould made some remarks about the position of gastric ulcers, to which we refer. He said: "Only 2 per cent. of the ulcers on the posterior surface of the stomach perforate, and only very rarely is this perforation into the general peritoneal cavity; more commonly the ulceration extends into the pancreas and gives rise to abscess beneath the diaphragm, and often, also, to suppuration in the pleura and base of the lung, especially on the left side. Of the less frequent ulcers on the anterior wall of the stomach as many as 85 per cent. perforate, and most often into the general peritoneal cavity," &c. It is becoming more fully understood that without operation in cases of perforation of gastric ulcer death will ensue, and that speedily. When operation has been performed the result has been satisfactory, and about 35 per cent. of the patients have been saved. It is the physician who must recognise when surgical interference alone can afford safety, and it was owing to the rapid diagnosis and action of Dr. Gordon Dill that the surgeon was in this case enabled to operate under unusually favourable circumstances.

An anæmic-looking woman aged twenty-four years was admitted to the Sussex County Hospital on the evening of Sept. 5th, 1894. She had for two years suffered pain after food, and five weeks previously she had been sick three or four times, but never brought up blood. The sickness induced her to seek advice at a London hospital,

to which she was admitted and was told that she had gastric ulcer. She was kept in bed and placed upon milk diet, but for the last week of her stay there had been taking chicken and fish without pain. She left the hospital and went to Brighton on Sept. 5th. About 7 P.M. the same evening she drank a large cupful of cocoa and shortly afterwards, whilst walking, was seized with violent pain in the abdomen and vomited. She managed to get into a cab and was taken home. About 10 P.M. she was seen by Dr. Gordon Dill, who having diagnosed a perforated gastric ulcer ordered her immediately to the Sussex County Hospital, where she arrived soon after twelve o'clock. On being summoned to the hospital Mr. Jowers found the patient cold and collapsed, the face drawn, the pupils dilated, the temperature 97° F. and the pulse 100, and complaining of great pain at the epigastrium. There was no distension of the abdomen, but great tenderness about the epigastric and left hypochondriac regions. The knees were drawn up and abdominal respiration was absent. Having heard the history of her recent treatment for gastric ulcer and elicited the fact of the sudden pain almost immediately after drinking, Mr. Jowers determined to operate at once, six hours after perforation. An enema of two ounces of brandy with two ounces of beef-tea having been given and ether administered an oblique incision was made about an inch below the margin of the ribs, three inches in length, and commencing about an inch to the left of the middle line. Having divided the muscles and stopped the hæmorrhage, which was somewhat free, the peritoneum was opened; there was no rush of flatus and the organs below appeared to be quite natural. Having with some difficulty brought the stomach into view by gently pulling down the omentum, its anterior surface was carefully explored with the forefinger. Failing to detect perforation, the omentum was pushed aside and the posterior surface similarly examined. Here the operator could feel, high up and towards the cardiac end, an indurated patch with a central depression, but the posterior layers of the omentum prevented actual contact. Having thus made out the situation of the ulcer, the incision in the abdominal wall was enlarged to the left, the anterior layers of the omentum were torn through, and the lesser peritoneal cavity was opened. A distinct odour of cocoa was now detected. With considerable trouble the perforation, which was of the size of a threepenny bit, was brought into view by gently pulling down the stomach wall bit by bit. Pinching up the outer coats of the stomach first on one side and then the other side of the ulcer, a full inch from the edges of the perforation two sutures of medium-size silk were passed, to act as guides and to assist in holding the stomach. The anterior wall, which had protruded during the manipulations necessary to bring the perforation into view, having been returned into the abdomen, Dr. Black, who assisted, held the perforation well in view by means of the guides. Sponges being packed around, one blade of a pair of scissors was then introduced into the perforation, and the indurated tissues, which extended half an inch around the opening, were divided in a line with the external wound. Curved incisions with the scissors were made from the extremities of these so as to excise the ulcer. A small sponge on a string was introduced into the stomach through the opening thus left, while fine silk sutures were introduced after Lembert's method, fourteen in all being passed. After the sutures had been tied the abdomen was carefully flushed with boiled water at 100° and the abdominal wound closed with silkworm gut suture, no drainage-tube being employed. The operation took about two hours, the chief time being occupied in the passing of sutures in the stomach wall. For the first five days the patient was fed entirely by the rectum, the injections consisting of peptonised milk and beef-tea, one large warm-water injection being given daily, and a morphia suppository when in pain. On the first day (Sept 6th) she was sick four times, bringing up a dark-green watery fluid, with very offensive, almost fecal odour. The temperature was normal. On Sept. 7th she was very slightly sick and the odour had disappeared. On the 11th, five days after the operation, feeding by the mouth was commenced by teaspoonfuls of milk given at intervals of half an hour, but as she complained of slight pain in the evening the milk was stopped. On this day the wound was dressed and two stitches were removed. On the following day feeding was recommenced, but as she vomited it was suspended until the next day, and brandy added to the injections. On the 15th there was found to be

¹ Erichsen: Science and Art of Surgery, vol. i., 1895.

a little superficial suppuration about the wound, and a drainage-tube was inserted. All went well till twelve days after the operation, when she was taking three ounces of milk and three ounces of mutton broth alternately at intervals of two hours. In the morning of that day she complained of pain in the region of the stomach going through to the back, and smaller quantities of food were given. About 1 P.M. the patient suddenly complained of intense pain and vomited. Mr. Jowers was summoned to the hospital and found her cold, collapsed, and complaining of intense pain in the region of the wound and "spreading all over the stomach," as she expressed it. The abdomen was flat, but did not move with respiration. Mr. Jowers had seen her at twelve o'clock and had suggested a tablespoonful of hot

water instead of the food then due; this had been given, and a second one half an hour later. After giving a hypodermic injection of morphia, and learning that the patient had become considerably worse during the half-hour since he had been sent for, he decided to reopen the abdomen. An injection of beef-tea and brandy having been given and the patient anaesthetised, the wound was opened up. The stomach was found to be adherent to the anterior abdominal wall in the region of the wound, and had to be separated. The site of the gastric ulcer was adherent to the posterior wall of the lesser peritoneal cavity, and as no sign of extravasation of stomach contents could be seen it was not separated. Half a pint of milk was then injected into the stomach, and, no escape taking place, the

* Ulcer believed to be in upper part of stomach. Adhesions were so dense that actual perforation was not searched for.

† The necropsy showed that death was due to a second perforation on posterior of stomach.

‡ Operated on three weeks after perforation for a collection of pus in left hypochondrium.

stomach was re-emptied and washed out. The abdomen was washed out and the wound closed, a drainage-tube being this time employed. After this operation the patient was much collapsed. Nutrient enemata were continued and injections of strychnia resorted to, but for some days it was doubtful whether she could recover. She was, however, able to retain the enemata, and after the first day small quantities of food.

Remarks by Mr. JOWERS.—I am unable to account for the symptoms which led to the second operation unless they were simply due to colic or possibly the stretching of adhesions. I had no doubt at the time that leakage, either from the sutured opening or from the giving way of a second ulcer, had occurred. About a month later the patient had a similar attack. Shortly after a meal, consisting of scraped meat (peptonised) and toast, she was seized with violent pain and became cold and collapsed as before, the pulse rising to 120. The abdomen, however, moved with respiration, and after a hypodermic injection of morphia the pain was relieved. Two hours later she vomited (no blood) and was much better. She has had no sickness or pain after food for some weeks, and has been getting up and going out of doors. In this case there were three favourable points—viz., (1) a clear history of gastric ulcer; (2) the opportunity of operating early before peritonitis had set in; and (3) the fact that perforation took place into the lesser peritoneal sac, thus avoiding the soiling of the general peritoneal cavity. I think it must also be an advantage when the patient vomits, as happened here, and so empties the stomach of a great part of its contents, though Dreschfield has shown that vomiting rarely takes place in these cases. I have not seen the use of guides noted in the cases recorded. I found them of such help in holding up the stomach and keeping the perforation well in view during stitching that I would advocate their use when there is difficulty. Their employment involves less strain than the plan of bringing the organ out of the wound, and would prevent a perforation when once found being lost, as occurred in one case where the operation had to be abandoned and in which it was only found again post mortem. I have been able to find references to twenty-five cases of operation for perforated gastric ulcer, of which a brief abstract is appended. Of fifteen, in which the site of the ulcer is stated, ten were at the cardiac end, three at the pyloric, and two in the middle. I cannot help thinking that the oblique incision gives the best access to the cardiac end, which is the more fixed and where rupture has been shown to be most frequent. In cases where there is a history of gastric ulcer, and where symptoms of rupture follow immediately upon taking food or drink, I should be inclined to adopt it, but when in the absence of previous history the diagnosis had to be based upon collapse, distension, loss of liver dulness, &c. I should adopt the median, as the rupture might be intestinal. My best thanks are due to those in whose immediate charge the patient was for the indefatigable care taken of her, and to which she owes her recovery.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Affections of the Nervous System occurring in the Early (secondary) Stages of Syphilis.

AN ordinary meeting of this society was held on Feb. 26th, Mr. T. PICKERING PICK being in the chair.

A discussion on the Affections of the Nervous System occurring in the Early Stages of Syphilis was opened by the President, Mr. HUTCHINSON. He said that although the discussion was designed to afford opportunity for criticism and the expression of opinions, its principal object was the collection of facts. The recital of single cases was asked for, and contributions to pathological knowledge were more especially desired. By the term "early" it was designed to comprise the first two years. Attention was asked to the following topics:—1. The general differences between affections of the nervous system in late and in early stages of syphilis. 2. The state of general diminution of sensation which had been alleged (Fournier) to attend the exanthem stage of syphilis. 3. Certain rare cases of general paresis of both motion and sensation which were met with in secondary syphilis, and from which

complete recovery might take place. 4. The early occurrence of arterial disease which might influence the nervous system secondarily: (a) in reference to the brain; (b) in reference to the spinal cord. 5. A group of not very infrequent cases, in which a rapidly developed form of paraplegia occurred early in syphilis, and from which, although it might be for a time almost complete, partial recovery usually took place. 6. The occasional occurrence of paralysis of single nerves (unsymmetrically). 7. The influence of syphilis in producing recurring herpes. 8. The parallelism between certain affections of the brain and spinal cord in secondary syphilis, with acute inflammation of the eye and ear occurring in the same stage. 9. The parallelism between these syphilitic affections of the nervous system and those of somewhat similar character which had been observed after the acute exanthemata. 10. The occasional occurrence of a peculiar form of partial anaesthesia. 11. The affections of the nervous system occurring in early periods of syphilis did not, when once cured, tend to relapse. 12. The necessity for the full use of mercury. From the facts he brought forward Mr. Hutchinson drew the following conclusions, which he offered as the basis for discussion: 1. The nervous system might suffer in various ways during the secondary period of syphilis, and it was very important to recognise this fact since the affections were usually acute and destructive unless prompt treatment were adopted. 2. It was very exceptional that any disease of the nervous system occurred earlier than the sixth month. 3. Many, perhaps most, of the affections of the nervous system in the secondary period were secondary to disease of the bloodvessels. Under this head were included extensive implications of the minute arteries of the pia mater, whether of the brain or cord. 4. Amongst the diseases which were probably primarily of the nerve structures themselves we might recognise (1) acute affections of the eye and ear, of the latter sometimes attended by paralysis of the portio dura; (2) acute forms of polyneuritis, usually symmetrical and transitory; (3) a peculiar and very definite form of paraplegia due to transverse myelitis; (4) certain rare and peculiar forms of hemi-anaesthesia. 5. It was not disputed that at much later periods in the course of syphilis affections closely similar to the above might occur, but it was believed that when they did so they were much slower in onset, less severe and more chronic in progress, and less amenable to specific treatment. 6. The prognosis of these affections was good up to a certain point if efficient treatment were commenced early. 7. It was believed that these early affections of the nervous system in syphilis occurred almost invariably in those in whom the treatment in the early stages had been neglected.

Dr. GOWERS said that he felt under considerable obscurity, which was not due to any lack of lucidity on the part of the President in introducing the subject, but was rather due to the subject itself. Of secondary syphilis in the strict sense of the word he knew nothing; at any rate, as far as the nervous system was concerned. With regard to syphilis and the nervous system, he only knew from personal observation of syphilitic disease of the larger arteries of the brain. He knew of no disease of the arteries of the spinal cord that could be called syphilitic. With regard to syphilis of the smaller arteries of the brain, there was an observation by Dr. Barlow which established the fact that there might be a syphilitic disease of the minute arteries scattered throughout the whole substance of the brain. The disease of the large arteries occurred usually during the first seven or eight years after the acquisition of syphilis, and was absolutely identical in its characters and effects and distribution from first to last, affecting the middle cerebral and basilar arteries by preference, and producing the same effects at all periods. He thought it could not be distinguished in any case as secondary or as tertiary by naked-eye or microscopical evidence, though its aspect was materially changed when the patient had been subjected to a course of anti-syphilitic treatment. A fact of practical importance with which he had been much impressed was that the dose of iodide of potassium as usually given, say fifteen grains three times a day, after two or three months ceased to influence the disease, which again became aggressive. Though the microbe of syphilis had not been discovered, it was necessary in order to obtain a real grasp of the disease to conceive it to be due to a specific organism. Besides the arterial disease there was the gumma, which was certainly of less frequent occurrence than was the arterial disease during twelve years after the primary infection; for

one case of gumma there were three or four of arterial disease produced by syphilis. Gummata always sprang from the membranes, never from the brain substance or from the substance of the spinal cord, and when present in the cerebral substance they could always be traced to some fold of the membranes. It was probable that a similar inflammation of the membranes was the origin of the indurated form of pachymeningitis sometimes met with in the cord. Small gummatous growths had also been found upon the nerves. Though locomotor ataxy was a sequel of syphilis in such a vast proportion of cases that there must be a causal relationship between them, yet the ataxy could not be cured by anti-syphilitic treatment. If locomotor ataxy were compared with the effects of alcohol upon nerves or of other chemical poisons, such as arsenic and lead, or those produced by diphtheria, there could be no doubt that the ataxy was the result of a chemical poison left behind by syphilis. The condition of inflammation might be associated with gummatous deposit in very varying degree, and the more acute the condition the more would the inflammatory phenomena preponderate. In the cases of acute cerebral meningitis which were sometimes checked or ended by mercury the inflammation was very acute, and there was little or no time for the production of characteristic gummatous tissue. He doubted at the present time even more than he did in 1880—when he published his work on "The Diagnosis of Diseases of the Spinal Cord"—whether syphilitic arterial disease played any part in the production of acute spinal myelitis. The fact that acute transverse myelitis was frequent in the subjects of constitutional syphilis had long been a familiar fact; but there was also this conspicuous fact about these cases, as about all cases in which inflammation preponderated over tissue production, that in proportion as this was the case anti-syphilitic treatment failed. Who that had kept in touch with the therapeutics of the past could have any doubt regarding the influence of mercury upon simple inflammation, and who was there who could place any confidence whatever in mercury as a test of the syphilitic nature or otherwise of acute inflammation? These cases, treated as energetically and promptly as possible, ran a course absolutely indistinguishable in every case from that of cases of transverse myelitis in which syphilis could be absolutely excluded. The syphilitic and non-syphilitic cases ran a parallel course. The same applied to arterial disease of the brain. It was only in the cases in which there was not the tendency to recovery which all acute processes involved that we could place any confidence whatever in the significance of the anti-syphilitic treatment. He quoted the case of a patient who had an indurated cellulitis in the region of the spine, who was not benefited by iodide of potassium, but who recovered under mercury. He found it difficult to judge whether to class this as a secondary or a tertiary lesion. From the therapeutical effect one should say it was secondary, but from the lapse of time since infection it should perhaps be declared tertiary. The President had suggested that gonorrhoeal myelitis might be the result of syphilis. So far as he knew, only two cases of gonorrhoeal myelitis were on record—one in a German journal and the other recorded by himself in the *Clinical Journal*.

On the motion of Sir WILLIAM BROADBENT, seconded by Dr. ALTHAUS, the debate was adjourned till the next meeting.

MEDICAL SOCIETY OF LONDON.

Cases of Liver and Gall-duct Surgery.—Craniectomy.

AN ordinary meeting of this society was held on Feb. 25th Mr. FREDERICK TREVES, Vice-President, being in the chair.

Mr. MALCOLM related in detail all the cases of Liver and Gall-duct Surgery that had come under his care—namely:—

1. A case in which by exploration he failed to make out exactly what was the nature of the disease. This case was illustrated by another in which no operation was performed, but malignant disease was diagnosed and verified by post-mortem examination. 2. A case in which by exploration he found malignant disease of the lower surface of the liver. 3. A case in which he performed ovariectomy and found malignant disease of the pancreas and duodenum, causing obstruction of the common bile-ducts. These patients had died from the natural progress of their diseases, and the surgical treatment could not be said to have hastened the results. 4. A case in which he operated three times for numerous hydatids of the liver and sub-

peritoneal connective tissue on Feb. 17th and Dec. 2nd, 1891, and on March 12th, 1894, the patient having borne a child between the second and third operations. She was reported to have recently shown signs of the development of another cyst. 5. A case of a child five years and a half old from whose liver he removed two hydatid cysts. 6. A case in which he removed 789 stones from the gall-bladder. 7. A case in which Mr. Doran opened an abscess over the gall-duct on Nov. 7th, 1893. Mr. Malcolm extracted 134 stones on Dec. 2nd, 1893, and Mr. Doran extracted three more stones on May 26th, 1894, after which the wound healed. 8. A case in which he removed four stones from the gall-bladder, cystic duct, hepatic duct, and common bile-duct. The last five cases had all recovered and were alive. The difficulties of diagnosis and manipulation were commented on, and the necessity of operation whenever gall-stones caused serious trouble was urged. It was pointed out that in liver surgery the dangers of septicæmia and of irritation and obstruction of the intestines could usually be avoided, and that the disposition of the colon and its mesentery facilitated drainage. An opinion was expressed in agreement with that of König¹ that the duration of an operation was not so important in causing shock as the nature of the manipulation performed. The following points were suggested for discussion. 1. The evidence by which a diagnosis can be made between gall-stones and cancer of the liver. 2. The possibility of gall-stones being overlooked in the ducts, and the possibility of their collecting in the ducts within the liver substance, and rapidly descending after other stones had been cleared out of the gall-bladder or liver ducts. 3. The length of time after infection at which a patient may be considered safe from a further development of hydatids. 4. The fact that in the third operation on the fourth case related there were removed a number of hydatids in which the daughter cysts were shrivelled up as if dead, although the tumour had been growing very recently and had shown no signs of diminution in size immediately before the operation.—Mr. DORAN thought that the gall-stones he removed passed down from the liver since Mr. Malcolm's operation. He asked for information as to the length of time it took for a gall-stone to form. If the stones could form in the bladder it might be advisable to perform a secondary cholecystectomy in some cases. This was not very difficult, because the procedure was practically extra-peritoneal, the gall-bladder being simply peeled out of its adhesions.—Mr. ARBUTHNOT LANE said he had operated upon a large number of cases in which the trouble was directly or indirectly due to gall-stones. His conclusions were that in these cases the diagnosis was comparatively easy and the results good if operation were not deferred until too late. As this form of surgery was still in its infancy surgeons were apt to be called upon to act at a stage in the case so late that the patient's condition gave little or no hope of success. The same was true of vermiform appendix cases and of cases of acute intestinal obstruction. He then gave details of four fatal cases in which he had operated. The first occurred four years ago, when he operated upon a female patient who had a stone of large size impacted in the common bile-duct. He incised the duct, extracted the stone, and afterwards attempted to close the incision in the duct, but he could only do this imperfectly. The patient died on the third or fourth day afterwards, probably from peritonitis. This death might probably have been prevented if he had used gauze packing. His second fatal case was that of a man who for fifteen years had suffered from jaundice with occasional exacerbations accompanied by fever and prostration. He found the gall-bladder and the ducts stuffed with calculi, and as the condition of the patient did not permit of a long operation, and as there was a fair quantity of bile in the gall-bladder he established a communication between that viscus and the duodenum by means of Murphy's button. The patient died two months later, when a small perforating ulcer was found in the duodenum proximal to the artificial opening. At the necropsy the ducts within the liver were found filled with calculi. The third case was that of a woman who entered Guy's Hospital in a feeble and delirious state, stating that she had been deeply jaundiced for four years. The colon was found fixed to the gall-bladder by adhesions, and in the common bile-duct were several stones, which were removed. The patient never recovered from the delirium and prostration. In the fourth case a woman, who had been jaundiced for five

¹ Brit. Med. Jour., Epitome, vol. i., 1895, p. 26.

months, when straining at stool felt a tearing pain in the region of the gall-bladder, and a tumour developed in that situation. She was nearly moribund on admission, the gall-bladder was found distended with clot, and a rupture extended through into the substance of the liver. She did not recover. In these four fatal cases he thought that his own surgery was responsible for but one death. He had operated successfully on a very large number of other cases.—Mr. HENRY MORRIS referred to a case in which he had dealt with multiple abdominal hydatids. Three times they were attacked by operation, and yet a large number were left, and they appeared to disturb the health of the patient very little, who followed an arduous occupation as a baker. His conclusions were that these cases of multiple hydatids were unfavourable for surgical interference. He once had to operate on a case of abdominal hydatid in which the tumour was very large and simulated ovarian dropsy, and had been treated elsewhere by tapping. He cut down in the middle line, and found the cyst to be connected with the under surface of the liver. He evacuated an enormous number of daughter cysts, removed the greater part of the parent cyst, but was obliged to leave the upper portion, which was too firmly adherent to be removed. The patient died from shock. There was still a great deal to be learnt concerning the development of gall-stones. He believed it depended greatly upon obstruction to the flow of bile. Many stones were formed in the ducts of the liver itself, others in the gall-bladder, and their formation was promoted by any cause interfering with the production of cholesterol, or of the bile acids which were the solvents of cholesterol. He had removed a number of stones from the gall-bladder of a woman, and the calculi were as tightly packed as were the bricks of a wall. After emptying the gall-bladder he probed the bile-ducts, but could feel no calculi. Some time later she passed two or three stones, and on one occasion he picked out eleven calculi from the sinus, which afterwards healed firmly. He believed that these latter stones were formed in the gall-bladder. The faceting of a calculus did not of necessity indicate that it must have been packed tightly with other stones; it might be produced by the churning up of a larger stone with smaller stones in the mucus of the gall-bladder. When gall-stones were impacted in the common bile-duct and there was long-standing jaundice, and if the gall-bladder were shrunken and contracted, the prognosis was unfavourable and convalescence after operation was slow; hæmorrhage was obstinate and death likely to occur from shock and peritonitis. But operation was more successful in cases in which the gall-bladder was distended with fluid so as to form a tumour.—Mr. GODLEE said he once opened a tropical abscess in the liver and found in it some small faceted gall-stones. Some years ago at Brompton Hospital he cut down upon an obscure tumour in the right lumbar region of a female patient. He found the transverse colon adherent, and there was a tumour in the gall-bladder and another in the liver. He gave a bad prognosis and closed the wound, but two years afterwards the patient passed a large gall-stone.—Mr. MALCOLM, in reply, said he thought that in Mr. Doran's case there was persistent obstruction in the cystic duct. It was curious that in the cases of multiple hydatids the tumours were usually confined to the abdominal cavity and the organs within it.

Dr. WALLIS ORD and Mr. EDWARD COTTERELL then related a case of Microcephalus treated by Linear Craniectomy. The patient was a female child aged nineteen months, who was first seen by Dr. Ord on July 28th, 1893, at the West-end Hospital for Nervous Diseases. The child was born at full term, there was no difficulty at birth, and no instruments were used. She was a healthy and well-nourished child until thirteen months old, when she had influenza, which was followed by "gastric fever." At the age of sixteen months she was suddenly seized with fits, which appeared to be general convulsions marked with an extreme degree of opisthotonos. She was said to have had sixty fits in five days. After the fits passed off the child began to waste and lose power in her limbs, and not to notice what was going on. Upon admittance the child was in a very feeble condition and quite unable to maintain a sitting position for more than a moment, quickly tumbling over. The normal relation of size between the face and the skull was reversed. There was no trace of fontanelles. The child was dull and apathetic and easily roused by loud sounds. She was not attracted by objects moved before her in order to catch her sight unless they were of a very bright

or luminous character. She was unaware of the presence of anyone approaching her cot quietly. Mr. Work Dodd examined the eyes, but could find nothing to account for the condition, and the loss of sight appeared to have been due to a weakness of the power of perception analogous to the weakness elsewhere in the body. In consultation with Mr. Edward Cotterell, linear craniectomy was advised, as the child appeared to be steadily losing ground. The operation was performed in sections, the dates when the bone was removed being Aug. 9th, 1893, Aug. 23rd, Sept. 4th, and Sept. 13th. Improvement began after the second operation and was steadily maintained, until she became like an ordinary child, running and walking about, and with every indication of very good eyesight. In these cases the bones of the skull were found to be much thinner than normal, and there was often little or no diploe to be found. When bone was removed the dura mater usually bulged into the groove. In performing linear craniectomy it was necessary to avoid hyperpyrexia and shock. Hyperpyrexia might be usually prevented by only taking away a small piece of bone at each sitting and by using care not to bruise the subjacent brain. Shock might be prevented by the above-mentioned means and also by applying an improvised Esmarch's bandage to prevent hæmorrhage.—Dr. SHUTTLEWORTH had had under his care three cases of microcephalic idiots which had not improved at all after operation. The first was a child three and a half years of age with a head circumference of fifteen inches. It had been operated on by Mr. Horsley, at first by longitudinal incisions and afterwards by transverse. Six months after the second operation it was noted that there was no mental improvement, though the child had ceased to beat its head. The second case, also operated on by Mr. Horsley, was the son of a medical man and had a head circumference of seventeen inches, and there were paralytic symptoms. One year after operation the child was worse, both physically and mentally. The third case was operated on by a Newcastle surgeon and remained a speechless idiot. In these cases there was an arrest of development of the brain at the fifth or sixth month of fetal life, and union of the bones followed this arrest of cerebral growth.—Mr. LANE asked if the case shown were really one of microcephalus.—Dr. ORD, in reply, said the case had been regarded as one of microcephalus or synostosis of the sutures. There was no evidence of tumour or of meningeal trouble. The case was not extreme; it was an instance of primary mischief in the bones of the skull, and not of primary atrophy of the brain.

HARVEIAN SOCIETY OF LONDON.

Syphilitic Diseases of the Brain.

A MEETING of this society was held on Feb. 21st, Sir JOHN WILLIAMS, Bart., President, being in the chair.

Dr. JAMES TAYLOR read a paper on Syphilitic Diseases of the Brain. These were classified in three groups: (1) meningitis, (2) gummata in the membranes with secondary affection of the brain proper, and (3) changes in the bloodvessels—endarteritis and periarteritis—and combinations of two or more of these. The symptoms commonly present in these three forms were briefly described, and also the symptomatology of another class of case characterised by considerable mental change similar to that occurring in general paralysis together with optic neuritis, but no distinct paralysis of the limbs. Dr. Taylor had no knowledge of the pathological changes underlying this clinical state, but suspected affection of the meninges and vessels. In two cases which he had seen, marked improvement, with subsidence of optic neuritis, had followed the energetic use of anti-syphilitic remedies, although some degree of mental change still remained. The treatment called for when syphilitic disease of the brain had been diagnosed was touched upon, and the extreme importance of using mercury freely, as well as iodide of potassium, instead of the latter alone, was insisted upon. Dr. Taylor, in conclusion, described the clinical condition in two cases which he had observed through the kindness of Dr. Hughlings Jackson and Dr. Ferrier, and also the results of post-mortem examination. One was a case of gummata in the membranes and the other of widespread disease—endarteritis and periarteritis—of cerebral vessels. Illustrative sections with a drawing and photograph were also shown.

The PRESIDENT related a case of syphilitic hemiplegia during pregnancy accompanied by thrombosis of the veins of

the chest. The condition was cured by mercurial inunction. He discussed the question of temperature in syphilitic meningitis.

Dr. GUTHRIE referred to the importance of certain minor manifestations of cerebral syphilis, and in particular of states of transitory aphasia and of ophthalmoplegia. He gave his experience of these in several instances.

Dr. CAGNEY spoke of the difficulty of recognising meningeal gummata at an early stage, and gave the history of a case in which the resulting abscess had extensively destroyed the inner tables of the skull and perforated the scalp, while the symptoms throughout had been ambiguous.

Dr. SHUTTLEWORTH stated his experience of congenital syphilitic brain disease in children. The symptoms began at the period of the second dentition. Dulness of intellect was followed by paralysis and later by imbecility with a proneness to use bad language and an ultimate breakdown. The necropsy showed an atrophied brain with thickened meninges.

Mr. Brodie, Dr. Hazell, and Dr. Macevoy also spoke, and Dr. Taylor replied.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held at the Great Northern Central Hospital on Feb. 14th, the President, Dr. J. G. GLOVER, being in the chair.

Mr. G. MOWER WHITE showed an infant the subject of Bilid Cranium with Meningocele or Encephalocele, or a combination of both conditions. The tumour, which was situated in the occipital region, was the size of a hazel nut and was reducible; the child was well developed in every other way and quite healthy. After discussing the condition, especially from the point of view of prognosis, Mr. White pointed out that this was a favourable case for operative procedure. In the first instance, however, he intended to apply an apparatus so as to protect the tumour, and at the same time to exert pressure on it in hopes that the condition might improve. If that failed he described an operative method which he had devised.—These remarks were discussed by Dr. GALLOWAY and Mr. CRESSWELL, who were opposed to surgical interference, as the tumour was small and unlikely to increase or come to harm.

Mr. BRYCE ORME showed the specimens from a case of Spontaneous Comminuted Fracture of the Femur in a patient aged thirty-six years, the subject of general paralysis. Suppuration ensued in the thigh and death resulted.—Dr. BAILEY mentioned a similar case from his own experience and remarked on the rarity of such cases.

Dr. EDWARD S. TAIT and Dr. LINDLEY SCOTT showed cases of Albuminuric Retinitis, and a discussion arose on the prognostic value of this condition occurring during the course of Bright's disease. The opinion generally held seemed to be that in most cases the condition was of grave import, betokening a serious degree of arterial degeneration, probably generally diffused; but cases were quoted which tended to prove that so far as any time limit was concerned little confidence was to be placed in its import. Cases occurred in which it appeared only a week or two before death in subjects apparently comparatively in good health, whereas in other cases it remained with little alteration for long periods, the patients remaining well.

Dr. JAMES GALLOWAY showed a man aged forty-six years who had been the victim of a severe accident in 1857, involving fracture of the frontal and parietal bones, followed by hemiplegia and other severe nerve lesions. Since that time he had worked in lead, and was subject to gout, lately having developed albuminuria. Having both these degenerative influences at work many complicated nerve lesions had resulted. He was shown on the present occasion on account of the striking alterations in certain associated movements of his eyes. It was found in any associated movement of the eyeballs to the right or left that the pupil nearest the object looked at dilated, and the other pupil contracted—that is to say, the pupil of the eye in which contraction of the internal rectus occurred also contracted, while the pupil in the eye of which the external rectus was in action dilated.—Considerable discussion resulted on this case, but no distinct explanation was forthcoming.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Osteomalacia subsequent to Scirrhus of the Mamma.—Exhibition of Specimens.

A MEETING of this society was held on Feb 13th, Professor SHERRIDAN DELEPINE, President, being in the chair.

Mr. C. E. RICHMOND related a case where Osteomalacia and Spontaneous Fracture of the Femur occurred in a patient who was the subject of a Scirrhus of the Mamma. The breast and axillary glands and fat were thoroughly cleared away, and there was no local recurrence. Visceral deposits, however, followed very rapidly, and the patient succumbed just over five months after operation. Before this, bony softening was observed in the pelvis, and the left femur (the diameter of which was much increased) snapped across when the patient was getting into bed. Fair union was obtained in four or five weeks, with disappearance of much of the thickening. Sections of the original breast tumour, of the liver, and of the iliac crest were shown, all exhibiting cancerous growth. The fractured femur also was shown, and a decalcified section taken from the site of bony union entirely negatived the presence of cancer at this spot, and merely showed the ossification of fibrous callus. Reference was made to a similar case in the Museum of University College, London.

Mr. J. W. SMITH showed a specimen of Fistula between the Gall-bladder and Duodenum, and a Gall-stone 1½ in. in length and 3½ in. in circumference, from a woman aged sixty-three who was admitted to hospital with a history of five days' acute intestinal obstruction, with stercoraceous vomiting. Laparotomy was performed and the gall-stone removed from the intestine. Death occurred seven hours later. The point of impaction was about the middle of the jejunum, the bowel above being greatly distended and congested. The cystic duct was obliterated, the hepatic and common bile-ducts remaining patent. The gall-bladder contained two smaller stones.

Dr. DRESCHFELD also showed a specimen in which a gall-stone had set up Ulceration of the Gall-bladder, with secondary biliary duodenal fistula, arrest of the gall-stone in the jejunum, and intestinal obstruction.

Card specimens were shown by Dr. Enrich, Dr. Helme, Dr. Kelyack, and Mr. Littler.

KIDDERMINSTER MEDICAL SOCIETY.

Castration for Enlarged Prostate.—A Case of Enterostomy.—A Case of Cerebral Abscess, Operation, Death.—Malarial Fever.—Exhibition of Cases and Specimens.—Fees under the Notification Act

A MEETING of this society was held on Feb. 8th, Mr. S. STRETTON being in the chair.

Mr. J. L. STRETTON read notes of a case of Castration for Enlarged Prostate. A man aged sixty years had had difficulty in passing urine for some months, and on the advice of Dr. Suckling of Birmingham had been using a catheter. For six weeks he had been much worse and had not passed any urine except by the catheter. He was first seen by Mr. Stretton on Jan. 4th. He was a healthy looking man. A No. 8 catheter entered the bladder easily, per rectum the prostate could be felt as large as a hen's egg, the right testicle was enlarged and nodular in places, and the urine contained a considerable quantity of pus and debris. On Jan. 15th the bladder was washed out three times daily, but the urine still contained pus and he was unable to dispense with the catheter. Both testicles were removed through a single incision. Ten days later he passed urine naturally for the first time. On the 28th he passed eight ounces at one time. The wound healed. He developed delusions and became very troublesome, and passed his urine in bed. This condition lasted for about a week or ten days, and he then began to improve. He could sit up and passed his urine naturally; its condition had improved, but the bladder was still being washed out with nitrate of silver solution. The prostate was about half its previous size. In the discussion which ensued several of the members were able to confirm the shrinking of the prostate. The report on the right testicle showed it to be tuberculous, and this, it was pointed out, rendered the case more unfavourable, but apparently did not interfere with the process of the operation. The

fact of one or both testicles being diseased certainly confirmed the desirability of their removal.

Mr. J. L. STRETTON also read notes of a case of Enterostomy. A man aged fifty-five years was sent by Mr. D. Fitch. He had always enjoyed good health. The day before being seen he was seized with pain in the abdomen, after a meal of bread and cheese the previous night; he endeavoured to evacuate the bowel without success; he had vomited constantly, and when first seen the vomited matter was faecal; he had passed no flatus. Rectal injections, castor oil, and opium had been tried without effect. The abdomen was distended and boardlike. On opening the abdomen there was evidence of slight peritonitis and a small quantity of fluid. The small intestine was much distended and congested; this was traced in both directions with a negative result. As the patient's condition was bad a coil of distended gut was opened and stitched to the abdominal wall. A copious discharge of liquid faeces followed. The following day he was much more comfortable, the distension had disappeared, and he had no pain, but his pulse was bad. During the next four days he several times became collapsed, and in spite of the free use of stimulants he died in this state on the sixth day. At a necropsy twenty-four hours after death the bowels were found to be nearly empty. No cause of obstruction could be discovered, and there were no signs of peritonitis. Mr. Stretton pointed out the difficulty of diagnosis in such cases, and maintained that the operation performed offered the best chance of recovery.

Dr. EVANS read notes of a case of Cerebral Abscess which he had operated upon. A girl aged sixteen years was admitted to hospital on Oct. 11th, 1894. She had always had fairly good health and no definite disease except ear trouble, which began two or three years ago without any known cause, and has since "run matter." One month previously, whilst at work, the patient was suddenly seized with a "fit," in which she remained insensible for two or three hours. The left side of the face and the left arm and leg twitched during the fit (this was corroborated by the medical attendant). Since this time she had been laid up. Headache began three or four months ago and had been "on and off" ever since, but after the fit and since had become more intense. Right internal strabismus had come on since the fit. The patient had been peculiar and strange in manner for about two years. The bowels were regular. She had only menstruated once about two years ago. The patient's mother had been in a lunatic asylum for twelve years, also her mother's brother. Her mother had had several children and no miscarriages; some of the patient's brothers were considered "queer" by their neighbours. On admission the patient appeared to have lost flesh, and stated she had. She lay on her right side and took no interest in her surroundings, not, as a rule, speaking unless spoken to, but would then give an intelligent answer. Cerebration was slow and she was very drowsy, but this was probably due to the bromide she had taken. The pupils were widely dilated, equal, and reacted to light and accommodation. She stated that sometimes she saw double with the right eye. Her expression varied sometimes; her face expressed pain; at other times there was a far-off, dreamy look about the eyes. She complained very much of pain in the frontal region, also of shooting pain down the right arm and sometimes in the left arm; the pain in the head was always worse at night and she often cried for some time with it. There was no loss of power in any of the limbs, and sensation was normal. The plantar and knee reflexes were absent; there was no ankle-clonus. Well-marked optic neuritis was present in both eyes, but the sight was normal with the exception of the double vision already mentioned. The sense of smell and taste was normal. There was a slight discharge from the right ear, a few drops of thin pus in the twenty-four hours, and this had remained the same since the first on-set according to the patient's statement. She heard the ticking of a watch one yard from the left ear, but could not hear it when placed close to the right ear; when placed on the skull in the neighbourhood of the right ear she could hear it. The temperature was normal and the pulse 72. Eight days after admission to hospital the patient vomited two drachms of clear fluid; the pain in the head and left arm continued to be severe. Seventeen days after admission she suffered from delusions and thought the nurses were black. These continued for two or three days, together with severe pain, preventing sleep at night. The hypodermic injection of one-sixth of a grain of morphia relieved these symptoms and she slept better. Loss of power in the left arm gradually supervened,

and much difficulty was soon experienced in getting her to take nourishment. She gradually became drowsy and semi-comatose. On Nov. 3rd a consultation was held on the patient, and it was decided that she was suffering from cerebral abscess, probably in the temporo-sphenoidal lobe, and that an attempt should be made to evacuate its contents. The patient was accordingly anaesthetised with chloroform and a semilunar scalp flap dissected down over the region of the lower part of the right fissure of Rolando. The periosteum having been raised from the bone, the trephine was applied over the region of the motor centre for the face. On the dura mater being exposed it was seen to bulge into the trephine opening, and there was complete absence of brain pulsation, the dura mater being very tense. The dura mater was opened by a crucial incision, and the brain substance probed in several directions with a fine aspirating needle; the needle was eventually introduced in a forward direction for a distance of about two and a half inches, when pus was seen to be exuding from the end of it. The abscess cavity was then aspirated and about three and a half ounces of oily and very offensive pus were evacuated. The opening in the brain was then enlarged by means of a long pair of sinus forceps introduced by the side of the needle, and the little finger was passed apparently into the abscess cavity. A small drainage-tube was next passed down to the bottom of the opening and the parts well washed with boracic acid lotion. The semilunar flap was replaced and fastened in position with sutures, an opening being made in its centre for the passage of the drainage-tube. After the operation the patient was at first very restless, crying out with pain in the head and moving the right arm. The restlessness continued through the night, gradually subsiding towards the morning, when she seemed fairly comfortable and inclined to sleep, and took her nourishment better. The wound was dressed the next day; there had been a good deal of oozing. On the second day after the operation the note was that the patient had been drowsy the greater part of the night after a hypodermic injection of one-eighth of a grain of morphia, and had taken six ounces of milk, one ounce of brandy, and some meat juice. This morning she looked bad and had a dusky complexion. The pulse was 168, weak, the respiration 40, and the temperature 100.2° F. She had coughed several times during the night. After this the patient gradually became comatose and sank and died on the morning of Nov. 7th, the fourth day after the operation. Previously to operation the temperature never rose above normal. On making a post-mortem examination an abscess the size of a large hen's-egg was found occupying the right frontal lobe; the abscess had a well-defined wall about an eighth of an inch thick, and in it was found the opening that the aspirating needle had made, but no other opening. Dr. Evans considered that there were several points of interest connected with the case. In the first place, as to the cause of the abscess, he could only suppose that the condition must have arisen from the ear disease. It seemed to him strange that the abscess should be situated in the frontal lobe so far from the seat of the original trouble; but in the absence of any history or sign of syphilis, tubercle, or other disease he could attribute the abscess to nothing else. The symptoms, too, were not very pronounced, at all events at first; the loss of power in the arm and leg was not at all well marked, and the headache was only severe at times. Of course there was the history of the fit—a solitary one—followed by slight strabismus, though the optic neuritis was well marked all the time the patient was under observation. There was very little vomiting and later some mental disturbance, as evidenced by illusions and hallucinations, but otherwise the faculties and intelligence of the patient seemed little disturbed. It seemed curious that so large an abscess, which—judging from the thickness of its wall—must have been in existence for some time, should have produced such a comparatively small amount of trouble. The diagnosis of the case, too, was thus rendered somewhat difficult, and the fact of the mother and uncle being insane was misleading. Dr. Evans stated that in future operations he should use an aspirating needle to search for the abscess, as in this case, but having struck the abscess he would pass a sharp-pointed bistoury down by the side of the needle in order to make sure of opening the wall, and so allowing a free escape for the matter. In the discussion which followed, it was suggested that had the operation been performed sooner the patient would have had a better chance of recovery.

Dr. EVANS also showed the case of a man who had fallen

from an apple tree and sustained a Compound Fracture of the Thigh, the bone projecting through the trouser, and also considerable injuries to the shoulder, probably fracture of the surgical neck of the humerus, with fracture of the acromion process of the scapula and of the neck of that bone as well. At the time the patient left the hospital he could walk with the aid of a crutch, and there was about three-quarters of an inch shortening of the injured leg. He could move his arm in almost any direction, placing his hand on his head without difficulty.

Dr. EVANS showed a Uterus he had removed per vaginam for Malignant Disease, having first ligatured the broad ligaments through an abdominal incision. The patient died from shock about twelve hours after the operation.

Mr. BETHUNE showed a large Fibroid about the size of a lemon removed from a multipara aged thirty-seven immediately after the birth of her ninth child. It was attached to the anterior uterine wall immediately within the cervix, and caused considerable obstruction to the birth of the child. It was ligatured and removed with scissors, and no bad symptom supervened.—Mr. HODGSON MOORE thought it would be better to wait until the uterus had resumed its normal condition unless the tumour prevented delivery.

Mr. M. JOHNSTON read a paper on Malarial Fever.

Mr. J. L. STRETTON brought forward the form of account demanded by the local authority for Notification Certificates. He doubted whether this, which was in reality a second report of each case, could be legally enforced. Since the meeting he has informed the members that his objection had been brought before the town council, and that their clerk had stated that the form could not be legally insisted upon, and it has therefore been withdrawn.

MANCHESTER MEDICAL SOCIETY.

Analysis of Fifty-five Cases of Carcinoma of the Breast.—Exhibition of Cases.

A MEETING of this society was held on Feb. 20th, the President, Mr. F. A. SOUTHAM, being in the chair.

Mr. C. E. RICHMOND showed a case following Destruction of Lymphatics from Lupoid Ulceration. Allusion was made to the compound character of the enlargement, consisting primarily of distension of lymph spaces due to absence of drainage by lymphatics, and secondarily to hyperplasia of areolar tissue caused by the irritation of such lymph accumulation.—Mr. C. E. Richmond also showed a case where he had performed Abdominal Section for a large Cyst probably splenic in origin.

Dr. BRAZIL brought forward two cases in which the symptoms of Appendicitis and Rheumatism were present simultaneously, and in which complete and rapid recovery took place under salicylate of soda. After referring to the literature of the subject Dr. Brazil discussed the relation between the two disorders.

Mr. JONES read a paper on an Analysis of Fifty-five Cases of Carcinoma of the Breast, based on an analysis of fifty-five operations for the removal of mammary cancer. The mortality attending the operation was under 2 per cent., and the proportion of recoveries was given as 12.6 per cent. Mr. Jones laid stress on the importance of a routine examination of the axilla through the operation wound, even although no obvious enlargement of the glands could be detected. In 48 of the 55 cases the axilla was thoroughly cleared out, and this with care need not add much, if at all, to the risks of the operation.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

The Adjourned Discussion on Cardiac Therapeutics.

A MEETING of this society was held on Feb. 28th to continue the adjourned discussion on Cardiac Therapeutics, Dr. CLOUSTON, President, being in the chair.

Dr. BYROM BRAMWELL, continuing the discussion, considered the general aspect of cardiac therapeutics. He dwelt on the difficulty of ascertaining the exact condition of the myocardium. He laid special stress on the reserve force of the heart and how important it was to note how it responded to tonics. The success of the treatment depended on the regulation of the minute details of the life of

the patient as much as on the giving of drugs. In neurotic, functional, or curable cases it was necessary first to remove the cause; secondly, to correct by appropriate treatment any deranged or abnormal condition which appeared to be present in the heart or in any of the other organs; then, if the patient were anæmic, to treat the anæmia; thirdly, to regulate the whole mode of life of the individual; fourthly, to reassure the patient as to the curable nature of the condition; fifthly, to administer remedies to soothe the irritable heart and to tone it up when in a condition of irritable weakness. In organic cases, such as acute simple rheumatic endocarditis, much might be done to limit the severity of the lesion by appropriate treatment. He emphasised especially the importance of rest in removing valvular strain. At the same time the heart muscle must be kept in good condition during convalescence by the use of tonics, as iron, arsenic, strychnine, &c. In chronic cases it was important to avoid strain, either muscular or arterial, to keep the heart muscle in the highest possible state of health and efficiency, and to protect the patient from everything which was likely to exert an injurious influence on the heart. In chronic cases, when compensation was well maintained, it was inadvisable to administer powerful cardiac tonics. When compensation broke down the treatment must be guided by the nature of the lesion and the condition of the cardiac muscle. In fatty degeneration due to deficient hæmoglobin large doses of iron should be given; in pernicious anæmia, arsenic. In cases of flabby and dilated heart Schott's plan of graduated exercise was very efficacious. Caution, however, should be used. In cases of senile heart in mitral regurgitation with high arterial tension the cardiac strain should be removed by reducing the blood pressure and the heart toned up. In those cases strophanthus was preferable to digitalis. He had found *exercise* a valuable means of treatment in neurotic affections, fatty infiltration, many gouty conditions, and many valvular lesions if the myocardium was healthy. Oertel's plan of treatment was chiefly useful in cases of fatty infiltration, Schott's in the same group of cases, and in valvular lesions provided the muscle was reasonably sound.

Dr. STOCKMAN remarked that with regard to the action of cardiac tonics they were as a rule used when the heart was exhausted and beating more rapidly and less forcibly than normal, and hence the amount of blood discharged at each pulsation was less, the arterial system became depleted and the venous engorged. The primary effect of a cardiac tonic was to alter the elasticity of the muscular fibres so that they expanded and contracted more completely without, at first at least, becoming more active. Thus the heart took longer to dilate, contracted more thoroughly and so filled better and threw out a greater amount of blood. The blood pressure rose and the heart became better nourished. The diuretic effect of tonics was due to the fact that the veins and lymphatics were able to absorb effused fluid and the kidneys discharged the extra water. Thus it was improbable that one member of the same group was a better diuretic than another. The action might commence more quickly and continue longer with one than with another, but the action was the same. He had seen a good deal of the action of strophanthus, digitalis, adonis vernalis and convallaria, and had got much the same results with all. Sometimes the drugs were strikingly successful, sometimes they failed. With regard to iodide of potassium pharmacologists differed considerably. That it dilated small vessels and caused a fall in blood pressure had been denied. Small doses were said by present authorities to act like digitalis, and larger doses to diminish blood pressure. The last case on which he (Dr. Stockman) had made observations was that of a man with spinal sclerosis, who was taking 300 grains per diem without any alteration in the pulse as shown by finger or sphygmometer. It did good in aneurysm, possibly because the disease might be syphilitic in many cases. He laid stress on the purgative treatment of cardiac cases with much dropsy. With regard to tapping the pleura he cautioned against what was practically starvation, brought about in this way by the abstraction of albumen.

Professor GREENFIELD said that he intervened in this discussion solely in order to bear testimony to the enormous value of strophanthus, which he regarded as one of the most important therapeutic agents discovered of late years. As he had not been present at the first meeting, his position as to the debate was that of the vast majority of medical practitioners, who would be influenced only by the necessarily brief abstracts in the medical journals. It would be

disastrous if the impression were conveyed that the leaders of medical opinion in Edinburgh regarded strophanthus with distrust, and as only applicable to critical conditions. He felt it a duty to give his emphatic testimony to its value, not as an exceptionable, but as the most commonly applicable of all the group of special cardiac agents. To its use he owed the life of many patients and friends, in conditions which before its introduction he would have regarded as hopeless, and in cases where all known remedies, including digitalis, convallaria, &c., had absolutely failed. For nine years he had used it in a large variety of conditions of cardiac failure, including cases of all forms and combinations of valvular disease: dilatation from senile degeneration and from acute strain or disease, as in acute pericarditis in pneumonia; in acute pneumonia, including influenzal, where cardiac embarrassment was so often the cause of death; in severe prostration from hæmorrhage; after severe operations, including those where peritonitis was present, &c., and in febrile conditions with consequent rapid action and tendency to failure of the heart; in febrile delirium tremens, &c. In the severe forms of acute dilatation, senile and other, its effect was most striking. And if only for its value in severe cases of acute pneumonia it would rank as an agent of unsurpassed value. He had, on a rough estimate, used it in about 400 cases of these diseases in hospital practice alone, apart from other cases. He need hardly say that it was used in conjunction with all other suitable remedies appropriate to special conditions—such as rest, or, in some cases, moderate exercise, posture, relief of bronchitis or other associated conditions, attention to food, condition of stomach and bowels, removal of dropsical effusions, &c.—on which he supposed all agreed. Nor need he mention further the value of combination with other drugs, as nitrites, alcoholic and other stimulants—tonics, such as arsenic, iron, strychnine, &c. He had frequently alternated its use with that of digitalis, in order to judge of their comparative value in various conditions. The result had been that whilst in some cases, especially in certain well-defined conditions with which all are familiar, digitalis proved equally or more efficient, in the vast majority strophanthus was safer, more certain, and less attended with danger, and succeeded where digitalis proved useless. Objections had been made to the want of uniformity of strophanthus preparations. This was no doubt true to some extent. But the defective action was soon perceived, and a better supply could be readily obtained. This fact pointed only to the necessity for proper pharmacological experiment before allowing its sale, for the defects were due mainly to the use of bad or used-up material, and the vendors should be prosecuted for the sale of bad preparations. But could anyone say that digitalis was better in this respect? All pharmacologists agreed that the preparations of digitalis were most uncertain in the amount of the various active ingredients contained in them. Moreover, its tendency to cumulative action, the uncertainty of the time of the appearance of dangerous symptoms, &c. rendered it necessary to restrict the employment of large doses to a limited period. On the contrary, the action of strophanthus was so rarely attended with this risk that it could be given continuously in large doses where needed. In only one case, the first in which he used it, had any serious toxic symptoms appeared, probably as the result of idiosyncrasy, and no such case had since come under his notice. In some critical cases, where there appeared to be almost no hope of recovery, he had given very large quantities—ten, fifteen, and even twenty minims every two hours—and with resulting cure. In such cases it was necessary to give it with the finger on the pulse, diminishing or increasing the dose as it appeared necessary. From the remarkable results of cure in formerly hopeless cases he was convinced that neglect of this remedy would result in the loss of many valuable lives. Hence he would urge those of his colleagues who were doubtful of its utility to try it again.

Dr. JAMES RITCHIE thought that drugs and exercise came a long way after rest as therapeutic agents in cardiac cases. He did not think cardiac tonics were necessary so long as compensation was maintained. He found strophanthus best for obtaining rapid action in serious cases, but he thought the action not so long continued as with digitalis, whose action lasted a long time after the drug had been discontinued. He thought digitalis gave a distinct tonic action on the heart which was not obtained with strophanthus.

Dr. WILLIAM RUSSELL remarked that what struck him most on the first night of the discussion were the omissions.

He thought they would have heard about the unsuccessful cases as well as the successful. There were, he said, cardiac cases which required no special cardiac treatment, as when there were no symptoms referable to cardiac insufficiency and the cardiac lesion was discovered accidentally, or perhaps when the symptoms complained of had no possible connexion with the cardiac lesion. Such cases were very common, and the existence of the cardiac lesion was apt to obscure the diagnosis or to mislead entirely. This was the more unfortunate as the essential cardiac tonics were contraindicated. The second class of cases were those in which functional cardiac trouble was a marked feature, and had to be dealt with at the same time, treatment being directed to the fundamental or primary conditions. Such cases were the anæmias, general debilities, and neuroses. In the same group might be included cases of heart overstrain in youth, with dilatation and apical and basic murmurs. In such cases digitalis was useful, with, of course, prohibition of the cause. In organic cases he thought nothing should be done for the heart directly unless there was evidence of insufficiency. Especial care should be taken to remove all cause of strain, both direct and reflex, especially digestive troubles, which were often erroneously attributed to the cardiac lesion. Of all the lesions aortic stenosis, in his experience, least required therapeutic interference when there was not cardiac insufficiency. It was extraordinary the amount of stenosis which might be present without apparently disturbing the individual. When aortic stenosis was accompanied by incompetence the conditions, as a rule, were different. He did not find digitalis applicable in all cases of double aortic lesion with want of compensation. He did not think with regurgitation digitalis was applicable when the pulse-rate was only from 60 to 70. Digitalis prolonged the diastole, and so led to greater regurgitation and over-distension of the ventricle. On the other hand, aortic regurgitation with a quick pulse, which could be slowed to 70 to 80, was benefited by digitalis. In cases of slow pulse he had found marked benefit from belladonna, probably from the drug relieving spasm in the smaller arteries and their capillaries, the spasm not only causing increased obstruction, but also anæmia of the heart muscle. He thought iodide of potassium, which produced considerable benefit in some cases, probably acted in the same way. In mitral incompetence digitalis acted admirably when the heart-rate was rapid. When the heart-rate was slow, iron and strychnine did better. In mitral stenosis the relation of heart-rate to treatment was the reverse of what it was in aortic or mitral regurgitation. A prolonged diastole was to be aimed at. When the heart was rapid good results might be obtained from digitalis. When anasarca was present it was better given hypodermically. He regarded, then, the heart-rate as the chief index to cardiac therapeutics. In addition, however, to rate, there was pulse tension. Where the tension was high, digitalis was contraindicated. His chief hope regarding strophanthus was that it might prove useful in cases where digitalis seemed to be contraindicated. He had had some cases which tended to encourage this hope.

Dr. CLOUSTON said that in certain cases of mania there was a very rapid heart action, running up to 130 or 140 per minute; the cause was probably central. He had had three cases of melancholia with a pulse never under 120. He had used digitalis with iodide and bromide of potassium in addition to the ordinary mental treatment. In other cases the opposite condition existed—stupor with œdema. Here cardiac tonics were useful. Cardiac derangements were very common in the insane.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Microscopic Sections of the Central Nervous System.—Topographical Anatomy of the Pancreas.—Cold-water Staroh as a Basis for an Injection Mass in Dissecting-room Work.

A MEETING of this section was held on Feb. 1st, Mr. FRASER, President, being in the chair.

Professor SYMINGTON gave a Microscopic Demonstration of a series of Sections of various parts of the Central Nervous System, stained by Golgi's method, which he had made last summer in Professor Kölliker's laboratory in Würzburg. Most of the specimens were hardened and stained by the

rapid method—viz., small pieces of fresh tissue were put into a mixture of one part of a 1 per cent. solution of osmic acid with four parts of a 3.5 per cent. solution of bichromate of potash. After being a few days in this mixture it was transferred to a 0.75 per cent. solution of nitrate of silver. All the sections were mounted in xylol balsam, and so far they had kept perfectly. He had found the method easier and more reliable than it was generally supposed to be in this country. He must, however, warn beginners that they need not expect to get such perfect pictures as those given in Golgi's great work, "Untersuchungen über den feineren Bau des centralen und peripherischen Nervensystems." The illustrations in this book were obviously diagrammatic and constructed from numerous sections.—Professor PURSER said that this method had entirely revolutionised our ideas of nervous physiology. Formerly it was thought that there must be complete structural continuity between cells for an impulse to pass; now it was believed that no cell was in structural continuity with another cell, but only in contiguity. Several difficulties occur in connexion with Golgi's method. The chief objection was that some cells stained and some did not. One could not say that where the staining stopped the process of the cell also stopped. It was necessary to work with young animals to get good results. His preparations were made from rats killed the day they were born.—Professor McWENNEY did not think it so very difficult a method. He did not find that it made any difference if he left the preparations in the solution some time longer than necessary. To clear the sections he first placed them in creosote, then in xylol and carbolic acid, and then in xylol. Finally, he mounted in Canada balsam, without using a cover glass. He found that there was a tendency to the deposit of a coarse granular precipitate on the physiological surface of the section.

Professor SYMINGTON read a paper on the Topographical Anatomy of the Pancreas. He had investigated the subject by hardening the abdominal viscera *in situ* by the injection of a 1 per cent. solution of chromic acid. The results differed in several respects from those of His. He thought that the pancreas was more easily investigated by the chromic acid method of His than by frozen sections.

Professor SYMINGTON also read a note on the use of Cold-water Starch as a basis for an Injection Mass suitable for ordinary dissecting-room work.—Professor CUNNINGHAM thought that for immediate use the addition of spirit to it was an improvement, as it could both preserve and inject at the same time.

SECTION OF PATHOLOGY.

Retro-peritoneal Rupture of the Duodenum. — Crystalline Branched Renal Calculus removed by Nephrolithotomy. — Fracture of the Sacrum.

A meeting of this section was held on Feb. 8th, Dr. J. A. SCOTT, President, being in the chair.

Dr. TAYLOR read a paper on Retro-peritoneal Rupture of the Duodenum. The patient was a drayman who was crushed between the point of the shaft of his own dray and the projecting hinder end of the shaft of another dray as he was walking backwards endeavouring to lead his horse through a narrow passage. He walked about half a mile to Sir Patrick Dun's Hospital, and asked the resident medical officer on duty to give him something to relieve his pain so that he might continue his work. No symptoms of severe internal injury being apparent he was allowed to proceed back to his work. The pain, however, increased considerably, and he went home and lay down. His condition became gradually worse, and next day he passed into a state of collapse, and died about thirty-six hours after the injury. The post-mortem examination revealed evidences of recent peritonitis in the region of the ascending colon and neighbouring coils of small intestine. Behind the colon were found considerable quantities of flatus and a watery faecal-coloured fluid. A rupture of the duodenum near the termination of its second stage was found. The edges of it were lacerated and somewhat swollen. It measured about an inch in its greatest diameter. There was considerable difficulty in finding out where the rupture had taken place, and it was only after a protracted search that its exact site was determined.—Dr. BENNETT thought, from the fact of the very rapid peritonitis, that there must have been an opening into the peritoneum. He had seen a case of retro-peritoneal urinary extravasation lasting six

weeks without producing peritonitis.—Mr. W. J. THOMPSON remembered a case which was taken into St. Vincent's Hospital. As there were symptoms of rupture the abdomen was opened. There was an escape of faeces, but no flatus. No trace of any rupture could be found, but after death a rupture the size of a threepenny bit was discovered at the junction of the second and third stages of the duodenum.—Dr. TAYLOR, in reply, said that as the subject of his paper showed no symptoms beyond what one would expect to find in any mild form of injury, and as he was himself anxious to go away, he was not detained. He had searched very carefully for any rupture into the peritoneum, but could find none. He agreed with Mr. Thompson as to the great difficulty of finding the rupture. When the abdomen was opened in the middle line it was extremely difficult to examine the duodenum. When he had the abdomen freely opened post mortem it took him nearly an hour to find the rupture.

Dr. C. YELVERTON PEARSON read notes of a case of Nephrolithotomy, and exhibited the Stone which he had removed from a man aged thirty-two years by the lumbar incision. The specimen was a branched calculus of oxalate of lime, weighing 200 gr. A great portion of its surface was covered with beautiful crystals of ammonio-magnesian phosphate.—Dr. ROCHE wished to know what were the points which would help to make the diagnosis between stone and tuberculous pyelitis.—Dr. BENNETT said that the diagnosis could be made by means of a microscopic examination for the tubercle bacillus. With regard to the structure of the stone he differed from Dr. Pearson, and thought it consisted of crystals of ammonio-magnesian phosphate.—Dr. ROCHE stated that he had the urine twice examined for tubercle bacilli by Professor McWenney, but none were found.—Dr. PEARSON, replying, said he attached great importance to the presence or absence of tubercle bacilli in making a diagnosis. He thought it was very rare, however, to have tuberculous disease of the kidney without having it also in the genital organs.

Dr. E. H. BENNETT exhibited a United Fracture of the Sacrum, in which the line of fracture was oblique. The lower fragment, unlike the transverse fracture of sacrum, was displaced upwards and to the left. Dr. Bennett discussed the question as to whether the injury in this case had been caused by a violent kick delivered from behind with the right foot.

THE HUNTERIAN SOCIETY.—The seventy-sixth annual general meeting of the Hunterian Society was held at the London Institution on Feb. 13th, Mr. Charters J. Symonds, president, being in the chair. Mr. Thomas Rushbrooke, M.A., L.R.C.P., &c., was proposed for election as an Ordinary Fellow. Mr. Cotman and Dr. Arnold Chaplin were appointed to act as scrutineers of the ballot. The report of the council for the past year was then read by the senior honorary secretary, Dr. Hingston Fox, and adopted upon the motion of Mr. Cotman, seconded by Dr. F. J. Smith. The financial report and balance sheet and the report of the Library Committee were read and adopted. It was proposed by Dr. A. T. Davies, and seconded by Mr. Cotman, that a hearty vote of thanks be tendered to the president for his valuable services during the past year, which had contributed so much to the success of the society. It was proposed by Dr. Pitt, and seconded by Mr. Ratter, that the thanks of the meeting be accorded to the vice-presidents, honorary treasurer, and honorary librarian for their services during the past year. A vote of thanks was passed to the council, the honorary secretaries, and the auditors. A ballot was then taken and the following gentlemen were appointed officers of the society for the ensuing year:—President: Charters James Symonds, M.S., M.D. Vice-presidents: Henry J. Thorp, John S. E. Cotman, R. Hingston Fox, M.D., and T. Mark Howell. Treasurer: F. Charlewood Turner, M.D. Trustees: H. I. Fotherby, M.D., and F. M. Corner. Librarian: Arthur T. Davies, M.D. Orator: G. Newton Pitt, M.D. Secretaries: T. H. Openshaw, M.S., and Fred. J. Smith, M.D. Council: Sir Hugh R. Beevor, M.D., T. H. Arnold Chaplin, M.D., Louis A. Dunn, M.S., Hope Grant, Francis R. Humphreys, Patrick Manson, M.D., John W. Oliver, M.D., George W. Potter, M.D., Henry J. Sequeira, St. Clair B. Shadwell, R. G. Tatham, and John F. Woods. Auditors: F. Gordon Brown, Hope Grant, Francis R. Humphreys, and Thomas Glover Lyon, M.D.

Reviews and Notices of Books.

An American Text-book of Gynecology, Medical and Surgical, for Practitioners and Students. By Various Authors. Edited by J. M. BALDY, M.D. With 360 Illustrations in text, and 37 coloured and half-tone Plates. Philadelphia: W. B. Saunders. 1894.

THIS text-book has been prepared by various American authors, all of whom are teachers of this branch of surgery in leading medical schools and hospitals, with the view of presenting a picture of gynecological surgery and treatment as they are practised in America. The work is essentially of a practical character, and is intended to be a working text-book for physicians and students. The list of authors consists of ten names—Drs. Baldy, Byford, Cragin, Etheridge, Goodell, Kelly, Krug, Montgomery, Pryor, and Tuttle. It is stated in the preface that the work embodies as nearly as possible the combined opinions of all the authors, although it is understood that each individual author must be free from absolute responsibility for any particular statement; the editor states that all extraneous matters and discussions have been excluded, and that he has attempted to allow nothing unnecessary to cumber the text, which he claims as thoroughly up to date. In reading this, as is the case with many similar American text-books, it strikes the English reader as being wonderful that patients should not be unwilling to submit to examination on some of the complicated couches, or, rather, so-called "chairs," such as the Indianapolis gynecological chair (Fig. 3). As a matter of good taste, we are ourselves inclined to think that, if it is considered necessary to figure the proper position for the dorsal examination, the genu-pectoral position, the lateral position, as well as the lithotomy position and the position of the patient on Trendelenberg's table, the necessary information might be conveyed by diagrams and descriptions rather than by actual photographs of naked women in these various positions. In the chapter on the Technique of Gynecological Operations a good deal of space is devoted to a description of the procedures necessary to render the hands of the operator aseptic, and to a description of the other precautions which it is the duty of those engaged in gynecological operations to observe. But we think it is a pity not to distinguish between what is really essential and what is not, for the more complicated the system the less likely is it to be practically carried out. Thus what is the use of advising gynecologists to avoid touching unhealthy or suppurating wounds, when they are daily making vaginal examinations by which the hands are necessarily frequently contaminated with all kinds of septic matter? A typical instance is the vaginal examination of an advanced case of cancer of the uterus. And, again, we do not see that it is of much practical use to advise operators only to wear gloves that can be washed. All such advice tends to divert attention from what is essentially necessary in order to avoid conveying septic infection, whether in the case of midwifery or of operative work. This we take to be the most thorough cleansing of the hands and nails with soap and water and a nail-brush, followed by thorough disinfection in a 1 in 1000 solution of corrosive sublimate immediately before touching the patient. The account given of the plastic operations required for ruptures of the perineum is clear and easily followed. It is noteworthy that the author of it is not greatly impressed with the advantages of the flap-splitting operation except in a limited proportion of cases. As regards the radical treatment of carcinoma of the cervix, in those cases which appear to be not too far advanced for operation the authors prefer total extirpation to the supra-vaginal amputation, on the ground that it is the more thorough of the two operations and

because they think the operator cannot tell whether the cancer is limited to the cervix or has extended to the body of the uterus. The question as to which is the better operation is a very difficult one, and it can only be settled by comparing a large number of cases in which extirpation has been performed with a large number in which only the supra-vaginal amputation has been performed, the disease being in an early stage in both sets of cases, and seeing whether recurrence is less frequent in the one series than in the other. One of the best sections in the book is that dealing with Fibroid Tumours of the Uterus. Speaking of the electrical treatment of fibroids the authors say "the percentage of cures about represents the possible percentage of errors of diagnosis." The account of the surgical treatment of fibroids by hysterectomy, with intra-peritoneal treatment of the pedicle, is excellent, and better than that to be found so far as we have seen in any other text-book. It appears to us that the operation (Daer's) by which all the uterus is removed, with the exception of the vaginal portion of the cervix, is preferable to the removal of the entire uterus in these cases. The steps of both operations are carefully described.

The book is well printed and beautifully illustrated, and will be more especially valuable as a work of reference for information on special points in the technique of many gynecological operations.

Edinburgh Hospital Reports. Published under the supervision of the Editorial Committee of the Royal Infirmary, the Royal Hospital for Sick Children, and the Royal Maternity and Simpson Memorial Hospital. Edited by G. A. GIBSON, M.D., D.Sc., C. W. CATHCART, M.A., M.B., JOHN THOMSON, M.D., and D. BERRY HART, M.D. Illustrated with Coloured Plates and Engravings. Vol. II. Edinburgh and London: Young J. Pentland. 1894.

THIS volume sustains in every respect the position taken by its predecessor, which it resembles in arrangement of contents, the first part comprising contributions from present and past members of the Edinburgh School, with a short but useful index; and the second statistical tables of the patients under treatment in the wards of the Royal Infirmary and the Royal Hospital for Sick Children, Edinburgh, from Oct. 1st, 1892, to Sept. 30th, 1893. The papers deal with a wide range of subjects in various departments of medical science, and are so numerous that we cannot do more than refer to those which appear to us to be of the greatest importance. Dr. John Wyllie writes on the Diagnostic Value of Patterns of Abdominal Tumidity and of Visible Peristaltic Spasm in cases of Chronic Obstruction of the Bowels and Chronic Obstruction of the Pylorus. Dr. R. A. Fleming contributes some Notes on the Physical Examination of the Intestines by the Method of Combined Percussion and Auscultation. Dr. D. Noel Paton has a contribution to the Study of the Influence of Fever on Hepatic Glycogenesis. Dr. Muir writes on Suppurations in Internal Organs. One of the most useful papers is that by Dr. Claud Muirhead on the Treatment of Enteric Fever. We hope this has been reprinted, so as to reach a larger section of the profession than those to whom this volume, however excellent, can be accessible. Dr. Affleck supplies clinical notes on cases of Gastric Ulcer, and Dr. R. F. C. Leith writes on Acute Perforating Ulcer of the Stomach, with some comparative references to the chronic form. Professor Sir T. Grainger Stewart and Dr. G. A. Gibson contribute a paper on Bulbar Lesions in Graves' Disease: a contribution to the Morbid Anatomy of Exophthalmic Goitre; the former also gives a study of a case of Nervous Disease exhibiting some features not hitherto described. Dr. Gibson and Dr. R. Muir write on Cardiac

Fibrosis as a result of Coronary Obstruction; Dr. J. Thompson on two cases of Valvular Heart Disease resulting from Fœtal Endocarditis; Dr. James Carmichael on Congenital Heart Disease—patent ductus arteriosus—Mitral Stenosis; Dr. James Mackenzie on Tricuspid Stenosis; Dr. Gibson on the Diagnostic Signs of Incompetence of the Pulmonary Valve. Dr. Lockhart Gillespie gives the cases of Organic Cerebral Disease admitted to the medical wards of the Royal Infirmary during the years 1892-93; Mr. Mowatt and Dr. Abernethy give the results of treatment in the ward for acute nervous diseases during the past year. Amongst the surgical contributions are Hints and Suggestions on the Practice of Surgery, and on the Intra-peritoneal Ligature of the Iliac Arteries, with notes of a successful case, by Professor Thomas Annandale; Practical Observations in Surgery, by Professor John Chiene, continued from the first volume; Notes on Operative Surgery, by Mr. Rutherford Morrison; on the Electrolysis of Vascular Tumours, by Dr. John Duncan; Tuberculosis of the Tunica Vaginalis Testis, with a clinical and pathological report of two cases, by Mr. Harold J. Stiles; Excision of the Ankle by External Incision, by Dr. James W. B. Hodsdon, also a case of Double Amputation for Senile Gangrene; the After-results of Simple Separation of the Epiphyses, by Mr. Charles A. Sturrock; and Notes on certain Groups of Cases of Surgical Disease, by Dr. Kenneth M. Douglas. Professor A. R. Simpson writes on Cancer in relation to Proliferating Ovarian Cystomata; Dr. D. Berry Hart, on the Pathological Classification of Diseases of Women with a Plea for a Revision of Current Views; and Mr. John Orr, on Abdominal Palpation and Auscultation in Obstetrics. The plates and figures in illustration of the text are clear and well executed.

From the medical report by Dr. A. Lockhart Gillespie we learn that 4243 patients were under treatment in the medical wards, the percentage of mortality on the total number of patients discharged was 9.59 per cent. and the average stay in hospital 30.6 days.

From the surgical report by Dr. Kenneth M. Douglas it appears that 4342 patients were under treatment, that the percentage mortality was 4.08, and the percentage mortality arising from 2469 operations was 5.4 per cent. This would be much diminished if septicæmia and erysipelas were banished from the wards—there are at least eighteen cases of the former recorded, of which sixteen proved fatal. In both these excellent statistical reports unnecessary labour is thrown on the registrars by the compilation of the column showing the average number of days spent by each group of patients in the wards, and it renders the table more confusing to the reader.

Mr. John Pirie supplies a short report of the cases treated in the Royal Hospital for Sick Children and in the Dispensary in Lauriston Lane.

LIBRARY TABLE.

Text-book of Hygiene. By GEORGE H. ROHÉ, M.D., Professor of Therapeutics, Hygiene, and Mental Diseases in the College of Physicians and Surgeons, Baltimore. Third edition. Philadelphia: The F. A. Davis Co.; London: F. J. Rebman. 1894.—While we fully admit the thoroughly reliable nature of the information recorded in this volume and the terseness and clearness of the literary style, we do not think the arrangement of the matter is always as happy as it might be, or the treatment of some subjects quite as full as they deserve. For instance, in the first two chapters the author deals with the hygiene of air and water and during the course of his remarks touches upon the analysis of these bodies, although a later chapter is specially devoted to this subject, in which the author is necessarily obliged to travel over some of the same ground again. In describing the different methods for the removal of sewage, while privies,

pails, earth closets, and the pneumatic system of Liernier are explained, water-closets are reserved for the chapter on "Construction of Habitations." Ventilation is dismissed much too briefly, and vital statistics are disposed of in thirteen pages; while quarantine is treated with extreme exhaustiveness. The remarks on School Hygiene are excellent; and in the chapter on Marine Hygiene several valuable food tables are introduced. The author is an advocate of earth burial and thinks that the possibilities of cemeteries becoming centres for the spread of infectious disease, or the means of polluting water supplies, have been much exaggerated. Against cremation he urges medico-legal objections and expense. At the end of each chapter is appended a list of questions, which will be found to be of service to students and others.

Diagnostik der Inneren Krankheiten auf Grund der heutigen Untersuchungs-Methoden. Ein Lehrbuch für Aerzte und Studierende. Von Dr. OSWALD VIERORDT. Vierte verbesserte und vermehrte Auflage. Mit 180 Abbildungen im Text. Leipzig: Verlag von F. C. W. Vogel. 1894. Preis 10 Mark. (*Diagnosis of Internal Diseases according to Modern Methods of Examination.* A text-book for physicians and students. By Dr. OSWALD VIERORDT. Fourth edition, improved and enlarged. With 180 illustrations in the text. Leipzig: F. C. W. Vogel.) London: Williams and Norgate. 1894. Price 10s.—This admirable and exhaustive work of the Professor of Medicine at the University of Heidelberg is already familiar to English readers in the translation of a previous edition published by Mr. Pentland. There is, then, no need to dwell on its special merits. It forms one of a large and increasing class of text-books, which are intended to systematise the study of clinical medicine. It is only when the reader comes to peruse such books that he can appreciate the notable extension made of late years in the methods and resources that are available to the physician in his investigation of disease. This extension has been mainly due to the aid derived from instruments of precision and the application of chemical analysis to the examination of secretions and other fluids. Professor Vierordt states in the preface that there is no chapter of the book which has not been revised in the present edition, and he justly draws especial attention to the number (and we would add the excellence) of the illustrations, many of which are coloured. He acknowledges his indebtedness in this respect to the excellent Atlas of the Clinical Microscopy of the Blood by Dr. Rieder, whilst the figures representing micro-organisms are credited to Herr Honsell, one of his students. The work is planned on comprehensive lines, and we have failed to detect any omissions of importance in its very complete scheme. It is, in brief, a book which cannot fail to be of the greatest utility, not only to the clinical student, but also to the teacher and to the practitioner of medicine.

Bégaiement et autres Défauts de Prononciation. Par le Dr. CHERVIN, Directeur de l'Institut des Bègues de Paris. (*Stammering and other Defects of Utterance.* By Dr. CHERVIN, Director of the Paris Institution for the Treatment of Stammering.) Paris: Société d'Éditions Scientifiques. 1894.—About the year 1846 the author's father devised a method for the relief of stammering, based essentially on the cultivation and maintenance of due coordination between the nervous centres and the vocal organs. His analysis of the act of phonation recognises three separate periods or stages—viz., formation of ideas; putting of the ideas into words; and, lastly, vocal utterance of the words. Stammering may be caused by failure in any one of these three, but principally in the third. Dr. Charvin's course of treatment is continued for three weeks, the first being devoted to such vocal exercises as do not involve stammering, and to the cultivation of a methodical regular respiration. All this time the pupil is bound to absolute silence, except while practising with the

teacher. During the second week ordinary conversation is permitted, but only in a very slow, somewhat drawling manner, incessant attention being given to the respiration and the orderly movements of the tongue and lips. The division of the syllables must be carefully observed, but without interruptions or jerkiness. In the third week these aids are partially dispensed with, and a natural, easy diction is practised. In 1874 this method was favourably reported on by a Commission of the French Academy of Medicine. Dr. Chervin strongly opposes surgical procedures and hypnotism. Stammering (or rather stuttering) is much more common in males than in females, but this order is reversed in the case of lisping (*blésité*), or the faulty pronunciation of certain consonants. It seems that in French there are at least fourteen words denoting this condition. It is not due to organic causes and yields to the treatment already described. The book well deserves the attention of sufferers from these complaints.

Klinische Abbildungen. Sammlung von Darstellungen der Veränderung der äusseren Körperform bei inneren Krankheiten. Herausgegeben von Dr. H. CURSCHMANN. 57 Tafeln in Hellogravüre. (Clinical Appearances Illustrated: Changes of Configuration produced by certain Internal Diseases. Edited by Dr. CURSCHMANN of Leipzig. 57 Photogravure Plates.) Berlin: Julius Springer. 1894.—The majority of these plates represent visible deviations from normality produced in the living subject by diseases of the nervous system. Some of them contain several figures showing the consecutive stages of a given act or movement. Thus Nos. 8 and 9 consist of eleven figures representing the transition from the reclining to the erect posture in a case of infantile dystrophia muscularis progressiva. No. 11 has two views (side and back) of the same disease in a man aged twenty-two years. No. 10 shows the pseudo-hypertrophic form in a boy aged eleven years. Nos. 18 to 23 represent syringo-mylitis; some of them show full length figures, others are restricted to the head and shoulders and the hands. Plates 28 (three figures, three-quarter length) and 29 (hands only) illustrate athetosis. Plates 30 and 31 give four consecutive three-quarter-length views of the same person, showing the position of the head and the successive facial efforts during speech in a case of sclerosis multiplex cerebro-spinalis. Plates 41, 42, and 43 represent Basedow's disease (exophthalmic goitre). The last of the plates shows pseudoleukemia lymphatica in a boy thirteen years of age, whose axillary glands, and more especially those of the left side of the neck, are enormously enlarged. All the plates are most effective both in execution and in selection of subjects. A copious explanation, in German, accompanies each of them. No. 27, representing paralysis agitans, is the only one which seems to convey but little information, as was perhaps unavoidable from the nature of the case. The plates and explanatory text, bound together, form a substantial and handsome volume. The plates are also published unbound, so that they may be conveniently handed round among an audience.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held on Wednesday, Feb. 20th, at 5.30 P.M. Mr. George Pollock, the President, occupied the chair. The following resolution was unanimously passed: "The committee of the Association of Fellows of the Royal College of Surgeons of England beg to express their deep regret at the loss which the Council of the College and the profession generally have sustained by the death of the President, Mr. Hulke, whose conduct in his distinguished position has earned the respect of all the Fellows of the College." The honorary secretary was asked

to forward the resolution to the Council of the College and to send a copy to Mrs. Hulke.

The meeting had been summoned especially to take into consideration the resolutions which the Council of the College at their last meeting passed in answer to the request of the meeting of Fellows in January for the appointment of a joint committee of the Council and the Fellows to consider the question of obtaining a new Charter. In substance the reply of the Council was that there were objections to the formation of such a joint committee, but that they had appointed a committee to receive deputations from the Fellows of the College in reference to the subject of the resolution. The committee of the Association decided to urge the programme which they had recently put forward, and nominated twelve members of the committee and Association as a deputation to the committee of the Council. This concluded the business of the meeting.

THE PAY SYSTEM AT THE GREAT NORTHERN CENTRAL HOSPITAL.

THE annual meeting of governors was held at this hospital in the Holloway-road on Feb. 22nd, Mr. C. T. Murdoch presiding. The committee's report stated that the pay wards were opened on Oct. 1st, and that the committee, after careful consideration and full discussion of the subject with the medical committee, had taken means to restrict the use of these wards to patients of moderate incomes who were desirous of contributing to the cost of their maintenance while in the hospital. In order to protect the interests of medical men in private practice, the patients' circumstances were inquired into, a certificate signed by the ordinary medical attendant had to be produced, and full particulars of every application were considered by the house committee. The maximum payment was two guineas per week, and this might be reduced at the discretion of the house committee; it only met the actual cost of patients in these wards, and there was no intention of making a profit.

The CHAIRMAN, in moving the adoption of the report, said that at the present time the hospital had accommodation for about 100 patients and had cost nearly £100,000. A small number of "pay beds" had been provided in accordance with the constitution of the charity, to which they were obliged to conform, whatever their individual views might be. Moreover, in raising funds for the hospital it was clearly stated in all the public appeals that a certain number of "pay beds" would be established. These, however, bore but a small proportion to the free beds.

The report having been adopted, Dr. GLOVER moved: "That this meeting of governors of the Great Northern Central Hospital regrets the recent changes in the administration of the hospital, by which pay patients have been admitted to its wards to be attended gratuitously by the honorary staff, and is of opinion that such a system is not likely to conduce to the welfare of the hospital or the advantage of the poor, for whom such institutions exist, and should without further delay be abandoned." He believed that the opening of these pay wards was not only detrimental to the local practitioners, but would tend to reduce the subscriptions contributed by the public.

Mr. GRAHAM seconded the motion.

Mr. BURDETT then moved as an amendment: "That with the twofold object of loyally administering the affairs of the Great Northern Central Hospital on the lines of its constitution, and of reducing to a minimum the competition between the hospital and private practitioners, it is desirable that the system of pay wards now in operation be so modified that the patients in these wards may, if they desire it, be attended in the hospital by outside practitioners of their own selection; that the pay system, thus modified, be continued for an experimental period of five years; and that a committee of governors be appointed to prepare a detailed scheme on these lines, and to report to a meeting of the whole body of governors, to be convened for this special purpose in June next."

Dr. POTTER seconded the amendment.

The CHAIRMAN having stated that the committee and the members of the medical staff would regard the amendment as a vote of censure on them, it was put to the meeting, but only Mr. Burdett and Dr. Potter voted for it.

The resolution of Dr. Glover having also been lost, the meeting shortly afterwards separated.

THE LANCET.

LONDON: SATURDAY, MARCH 2, 1895.

ONCE more London is visited by an outbreak of this mysterious disease—the fifth in as many years. Few, if any, previous epidemics are recorded in which the country was visited in so many successive years. The epidemic last year was comparatively mild and half-hearted, but it has now suddenly assumed all the vigour of its earlier performances in 1889-90. Although isolated cases have been met with in London since November they were mostly mild, and showed little tendency to spread through a house and were accompanied by few complications. During the last week, however, a change has come over the scene. The disease has spread rapidly over the metropolis and many other towns, and rarely enters a house without attacking more than one of the inmates, and, most serious of all, unless the utmost prudence be observed bronchitis and pneumonia of a serious form are apt to supervene, and in not a few cases have proved fatal. We have spoken of the affection as a mysterious disease because, although it has been watched by a host of accurate observers—most of whom have had personal experience of its effects,—we are still in the dark as to its causes, as to the conditions which influence its outbreak in epidemic form, and as to the change of type from year to year which is such a singular characteristic of its natural history. Dr. CREIGHTON finds this change of type in previous epidemics clearly described by MOLYNEUX in the seventeenth century and by WARREN of Boston in the eighteenth, the latter stating in a letter to LETTSOM that the symptoms in two successive years were so dissimilar that it seemed as if two different diseases were in question. The Local Government Board report of Dr. PARSONS and the able monograph of Dr. RICHARD SISLEY both deal in a masterly way with the natural history of the disease and its mode of spread; and these and a host of other publications have detailed the clinical symptoms and the sequelæ of the disease. With regard to the symptoms, the most striking feature of the mass of literature on the subject is the variability of the symptoms and the absence of any constant characteristic. This applies even more markedly to the sequelæ, but the pulmonary conditions, which differ little from those excited by other causes, are probably the most common and next to them various nervous affections. Prolonged debility, muscular pains, and indefinite functional nervous symptoms grouped under the convenient term “neurasthenia” were particularly frequent; but except for the history of a previous attack of influenza there was nothing about the symptoms themselves to distinguish them from those met with in patients who had not suffered from influenza. So with regard to insanity. Undoubtedly an attack of influenza has in many cases brought about an acute attack of insanity, but in a recent discussion on the subject those best qualified to judge were of opinion that no form of insanity had come under their notice which was pathognomonic of influenza.

With the extension of work such as that of Dr. PARSONS and Dr. SISLEY much may yet be discovered as to the origin of the epidemics and the means of preventing them. The alleged discovery of a micro-organism as the cause of the disease has lacked general confirmation and has led to no fruitful developments. As to the question whether we have any effective prophylactic to protect the individual during an epidemic the reply must be in the negative. Quinine has been highly vaunted, but while by its tonic action it may help to resist infection, its action is far too uncertain and too occasionally successful to enable us to regard it as a specific antidote. During the first year much was heard—and smelt—of eucalyptus. Blotting-pads were saturated with it, hosts sprayed their guests with it as they entered the house, but influenza made its way into the houses that reeked of eucalyptus with as little ceremony as into those where things were left to take their course. We do know, however, that any depressing influences, such as a chill, indiscretions of diet, overwork or emotional conditions, especially dread of infection, not merely render a person liable to fall a victim to the complaint, but also tend to make the attack more severe, and common sense would suggest at such a time more than ordinary prudence in observing the laws of health. The rapid increase in the death-rate in the last few weeks warns us that the disease is not to be trifled with. There is this year a notable tendency to relapses, often accompanied with serious pulmonary symptoms, and the utmost caution should be observed before allowing patients to return to their ordinary occupations. By neglect or imprudence a trivial attack which would otherwise pass away in a few days may develop into a severe illness which may jeopardise life and incapacitate the patient from active work for many weeks.

DR. F. T. ROBERTS, in his Lettsomian Lectures on Combinations of Morbid Conditions of the Chest, easily makes good his contention that such combinations are very common and that their importance and significance are inadequately recognised. The error of fixing the attention upon one morbid state or one prominent clinical symptom is very general, and to immature minds and unskilled observers is practically irresistible; but we all need occasional reminders that there are no hard-and-fast lines in nature, and that the elaborate classifications and hard-and-fast distinctions so usual in text-books, though often practically useful, give an erroneous impression of a fixity and precision which as a matter of fact do not exist. Disease is not mathematical or mechanical. It is fluid, mobile, easily passing from one transition to another, incapable of precise definition, obeying general laws and definite principles, but not to be confined within the limits of rigid rules or unvarying formulae. Specialism in medicine is always open to the reproach that disease refuses to recognise the limits of the specialist's domain. Dr. ROBERTS wishes to utter “an emphatic protest against the absurd development of specialism in relation to this region—i.e., the chest—which at the present day is working so much mischief”; and he gives it as his opinion that “the practice of dealing with each thoracic organ as if it were entirely separate and distinct, or, still more, of making a

speciality of different complaints, is both dangerous and absurd." It is evident, we think, that any attempt to study pulmonary disease apart from morbid conditions of the heart must be doomed to failure; and to this extent, at all events, we entirely concur in Dr. ROBERTS'S *caveat* against excessive specialism. But we must beware of running from one extreme to another.

After a passing notice of the importance of conditions of the chest wall and diaphragm Dr. ROBERTS proceeds to discuss a group of cases characterised by a combination of conditions difficult to define, but of great practical importance. "In these cases the superficial structures are more or less wasted, it may be considerably; the chest walls are obviously rigid; localised pleuritic adhesions can be made out, it may be in several spots; there are no gross lesions to be detected in the lungs, but these organs are evidently wanting in normal elasticity and tending towards degeneration, perhaps also exhibiting limited areas of emphysema, or there is a suspicion of a fibrotic change here or there; sometimes there are indications of commencing atheroma of the aorta, or the heart is feeble in its action and is probably of actually small size." Everyone is familiar with these cases which, as the lecturer says, do not belong to the chronic emphysematous or phthisical groups, and are often, for want of a better title, simply labeled cases of "weak chest." The important practical point about such cases is that they do well by using suitable precautions and having an occasional change of climate; but that even a slight bronchial attack is a serious matter for them and that they die readily from pneumonia or other grave acute affection. The prognosis and treatment of such cases require to be regulated by a due recognition of the fact that symptoms trivial in themselves acquire a serious gravity when viewed in relation to this peculiar type of patient. Dr. ROBERTS protests against the crude and superficial way in which many of the laity talk of phthisis, as if the mere recognition of the bacillus explained everything. He points out the absolute necessity of recognising the numerous grave organic changes wrought by the disease, such as consolidations, tuberculous, inflammatory, caseous, or mixed; milky tubercles, diffused or in groups; softening of these structures; cavities, reparative changes, the formation of fibroid tissue, bronchial inflammation, compensatory emphysema, and the like. Cases of chronic pneumonia, in whatever way arising, "in time assume a decidedly complex character. The fibroid change is limited in most cases mainly or entirely to one lung, or a portion of it, which is thus hardened and contracted, the involved structures being rendered quite useless; it is also often accompanied with the remains of phthisical cavities, and still more frequently with dilated bronchi, while unaffected areas of the same lung, as well as the opposite one, become the seat of compensatory distension, which may ultimately terminate in true emphysema. There is an exceptional class of chronic pneumonic cases which may prove very puzzling. In these one lung is absolutely solid, either throughout or over a large extent, but instead of being contracted it is more or less enlarged. The opposite lung becomes greatly distended, and also in some instances the seat of dry bronchial catarrh; so that the general aspect of the patient, as well as the prominent symptoms may

resemble closely at first sight those of an extreme case of emphysema and bronchitis, with an asthmatic tendency."

Asthma and angina pectoris afford Dr. ROBERTS good instances of the necessity of a comprehensive view of chest ailments. In a large majority of cases asthma "supervenes upon distinct and obvious morbid changes associated with the chest, which tend to become more and more pronounced as the case progresses. The cases in which asthma occurs are usually more or less of the emphysematous and bronchitic type; but rigidity of the chest walls, adhesion of the upper part of the lung, and other factors are often of much importance in these cases in relation to asthmatic attacks." Angina pectoris "usually complicates more or less definite morbid conditions of an organic nature. Those which are most likely to be overlooked are atheroma or calcification of the aorta and coronary arteries, and cardiac degeneration not of a pronounced character." Dr. ROBERTS'S concluding remarks on the treatment and general management of combined chest cases are wise and judicious, but do not present any novelty. He is emphatic on the importance of recognising what may fairly be expected from treatment and what it is folly to attempt; on the necessity of wisely adapting our measures to acute conditions supervening on chronic; on the need for grappling promptly with grave conditions readily amenable to treatment—e.g., effusions into serous cavities; on the value of rest and the simpler drugs; on the impolicy of fussy therapeutics and routine symptomatic treatment; and on the wisdom of being on our guard in relation to new "cures" and vaunted specifics.

It is, we think, impossible to read these lectures without a heightened sense of the complexity of many chest cases, and the absolute necessity of viewing them in all their bearings and relationships before venturing upon either prognosis or treatment.

WE have frequently called attention to a subject which recent occurrences in India have again forced upon our notice—viz., the very serious amount of inefficiency caused in the European army of that country by the prevalence of a certain class of diseases. The Commander-in-Chief in India, speaking quite recently on the Cantonments Acts Amendment Bill in the Legislative Council at Calcutta, said that practically 50 per cent. of the strength of the army were admitted into hospital in the year 1893 for these diseases, and that he believed the record for 1894 would be found to be worse. There cannot be any doubt, therefore, about the extent of the evil. The Commander-in-Chief added that neither personally nor as representing the army was he in favour of the removal of what he believed to be most useful restrictions; but he considered that it was his duty to support the mandate of the House of Commons, however much he differed from the policy enforced. We have no sympathy with that class of people who, persistently shutting their eyes to the magnitude of the evil, have fanatically opposed every attempt to check or limit its spread by legislative means. We set aside the question of whether these attempts, either in this country or India, practically effected their purpose, as this touches upon contentious matter about which there may be room for difference

of opinion. For the moment we confine ourselves to the question of the principle involved. We hold that it is the duty of the State to do all in its power to check and mitigate the evil, for the same reason and on exactly the same grounds that the State recognises the dangerous nature of other contagious disorders and tries by every means in its power to check the spread of such a disease as small-pox, for example. We cannot shut our eyes to a fact that we encounter in the history of every past civilisation, and can any day see with our eyes in the streets of any city and large community at the present time. Prostitution forms a trade or calling which, under certain conditions, is a most dangerous one to the community at large. The results are not simply restricted to those who, by yielding to temptation, expose themselves to the risk of infection, but perfectly innocent and unoffending people in this respect are notoriously frequently involved in the consequences. In order to safeguard the public health against accident or injury we do not hesitate to impose laws and restrictions in the matter of dangerous trades and infectious diseases. The world cannot be governed on abstract principles of right and wrong without reference to the constitution and frailties of human nature; the conditions of society as it exists now, and probably always will as long as human nature remains what it is, must be taken into account. It seems to us ridiculous to characterise measures for the limitation of the spread of contagious disease as State regulation of vice, for they are nothing of the sort. Whether the measures that had been adopted have succeeded or failed, been adequate or inadequate for the end in view, the practical tendency of them was, it seems to us, to check indecency and open prostitution, to deter young, vain, and thoughtless girls from being led away by temptation and dissipation from fear of being discovered, and by affording succour and aid to those "unfortunates" who were diseased it placed them under conditions favourable to the access of kindness and moral influences, and in that way added to their chances of abandoning their mode of life. All this appears to us to be the very reverse of a State regulation of vice. With regard to the means by which the spread of venereal diseases can be checked, the question is admittedly one of great practical difficulty. The Contagious Diseases Acts hospital system in this country and the Cantonment Act system in India have not, it is urged, as a matter of statistics and experience, been productive of all the good that was anticipated; but that does not at all prove that they were inherently wrong. It only shows that they were inadequate to effect all they were intended to do. There are many reasons why this should have been so into which it is needless to enter now. Of one thing there can be no doubt — namely, that according to official returns the inefficiency in the army in India from these causes has greatly increased of late. The extensive prevalence of these diseases is a very serious matter, the consideration of which, however much it may be put off for the present, must ultimately compel attention. The voluntary lock hospital system is evidently not calculated by itself to effect much good, and sooner or later some additional practical means will have to be devised for dealing with this subject, based presumably upon the principle that those who are known to be suffering from a highly contagious

disease should not be allowed to follow a vocation which endangers all those with whom they consort. In the present state of the political temper any attempt of the kind would be but "ploughing the sand of the seashore," but we have confidence in time, reason, and common sense.

It may or may not be a matter for regret that the question of London's future water-supply will have brought to bear upon it the influence of party differences of opinion; it is, at any rate, not a question that will admit of precipitate action. The subject, especially in regard to increasing the supply and to the municipal acquirement of the existing undertakings, is being pressed home upon us at the present moment with a zeal which possibly exceeds wisdom, and which may possibly also be lacking the ballast which is the *sine qua non* of sound and healthy legislation. On the one hand, the London County Council have decided to apply for powers for obtaining additional supplies. Their case is that the scheme of a system of storage reservoirs, coupled with the proposal to abstract large additional quantities of water from the rivers, is not the proper method of meeting the future wants of London, and that any further capital expenditure on works in the Thames and Lea valleys should be regarded as of a temporary character, and should be restricted to such improvements as may be for the time indispensable; and finally, that the true solution of the problem is the obtaining of the necessary additional supplies from a purer source. On the other hand, there are the conclusions of the Royal Commission of 1892, which, seeing that they were based upon the evidence of leading experts in the engineering, geological, bacteriological, and chemical sciences, and upon the evidence of experience, cannot be ignored. On the question of the desirability of the acquirement and management by the municipal authorities of the supply of the "first necessity of life" there can be no divergence of opinion. The lesson taught on this head by the experience of Birmingham, Glasgow, and other large towns is conclusive. It may not follow, however, that the practical administration of water distribution will be any better for municipal control, except in so far as it will be influenced by public opinion; whereas at present the consumer is left largely dependent upon the resources and decision of private bodies. We know even in these days that although such matters of importance as highway maintenance, street lighting, and the removal of dust are in the hands of public authorities, yet in some cases their administration has fallen short of what the public have required in regard to comfort and even to health. It is, however, most probably the question as to what will constitute fair and reasonable terms for the acquirement of the present companies' undertakings which will give rise to the widest dispute and dissension, and which will be the chief source of delay before the transference of the water administration to the municipality becomes an accomplished fact. It is clearly a matter for arbitration which ought to be perfectly fair and open, and in which all the points in favour of either side should be considered by the arbitrators so that they may give both for seller and buyer a reliable and fair estimate.

What this estimate may be it is, of course, impossible to judge; but, even assuming that it is likely to be favourable to the purchaser—i.e., the public—it must necessarily mean a heavy impost upon the rates for some time to come. It will involve, according to the County Council's own estimate, a certain expenditure of £33,000,000, and when to this is added their proposal to obtain a fresh supply from Wales at an additional estimated cost of £20,000,000 the London ratepayer may well take breath. He may reasonably ask, Is the enormity of the proposed scheme consistent with our present needs, or is this gigantic financial undertaking an immediately necessary step? The conclusions of the Royal Commission, to which we have already referred, would reply distinctly in the negative, and the reports issued from time to time in the annual Blue-book of the Local Government Board by General SCOTT in regard to supply, and by Professor FRANKLAND in regard to quality, have to some extent anticipated these conclusions. The report of the last official year (1892-93) has been recently published, and the section relating to water-supply is dealt with in another column of our present issue, from which it will be seen that both the adequacy and the efficient purity of the supply are maintained according to the opinion of these experts.

The Royal Commissioners calculated that the present resources, aided by increased storage, would be sufficient "to supply thirty-five gallons a head to a population of 12,000,000, which is about 750,000 in excess of what the total population of Greater London, together with the outlying parts of water London, will have become in 1931 even if the ratio of increase in the decennial period from 1881 to 1891 is fully maintained." The conclusions as to its fitness for drinking purposes are couched in equally optimistic terms. Thus they say: "Having regard to the experience of London during the last thirty years and to the evidence given to us on the subject (which includes 'the unanimous testimony of medical officers of health, water analysts, bacteriological experts, and others'), we do not believe that any danger exists of the spread of disease by the use of this water, provided that the water is *efficiently filtered*, before delivery to the consumers." (The italics are ours.) That we do not go so far as to accept unreservedly the conclusions of this report may be gathered from an article on this subject in THE LANCET of March 10th and 24th, 1894, in which we traversed several vital points; but we may reasonably submit that the conclusions to which the Royal Commission came after a most careful, laborious, and prolonged inquiry deserve very serious deliberation before we are asked to embark upon an enterprise the avowed aim of which is admirable, but the immediate necessity of which seems to us to require further evidence. In the meantime we may urge again, as we have urged before, that, inasmuch as the purity of the present supply depends most seriously upon the efficiency of filtration, it is extremely desirable that provision should be made with not a moment's delay for an administration to fully secure and maintain such efficiency. In regard, however, to the powers which the County Council are seeking from Parliament, we doubt not the benefits of the scheme; but have the financial effects been really seriously considered?

Annotations.

"Ne quid nimis."

FEVER AND SMALL-POX HOSPITALS.

OUR issue of last week contains a letter from Dr. C. E. Matthews, who takes exception to our comments in a leading article, published in THE LANCET of Feb. 16th, on the subject of "Fever and Small-pox Hospitals." Dr. Matthews begins by stating that we express disagreement with those who seek to limit the power of diffusion of small-pox. We are not aware that we have done so. All we did was to point out that the evidence on which Dr. Matthews based his views as to a definite limit was not such as to warrant his conclusion. To quote Dr. Matthews' own words, he has laid it down that "the extreme limit of diffusibility" of the small-pox infection is "1000 ft." This is based on the negative evidence that whilst 1563 small-pox patients passed through his hospital in certain months of 1893, the inmates of a fever hospital and of the Darenth Asylum and schools, situated "about 1000 ft." distant, did not contract small-pox. We indicated that two points at least having an all-important bearing on the question had been ignored. One was the condition of the "school inmates" as to vaccination. Dr. Matthews answers that the inmates of "the institutions" referred to—three in number—were on about the same footing as regards protection from small-pox as the general public. But the speciality of "school inmates" is again ignored. The inmates of public schools are generally protected by vaccination to a degree of efficiency altogether unknown as regards the general public, and, being largely composed of young children, they afford a double test by reason of age, which is altogether special to them. If they are unvaccinated they fall an exceptionally easy prey to small-pox; if vaccinated they have had the benefit of the comparatively recent operation and, as the Registrar-General has shown, of a protection against that disease which is also altogether exceptional. Dr. Matthews wonders that we ask as to the vaccination of the school children, and yet he made it a point in his report to tell us of the fever patients, who likewise escaped, that "special precautions" were taken to transfer from London "only patients who showed evidence of previous vaccination." The fact that special precautions in the selection of these patients were deemed necessary indicates pretty well that the managers and their advisers were not content to put to the test the amount of protection against small-pox possessed by "the general public." The next point which we set out as having an important bearing on the case was the stage at which the small-pox patients arrived in the hospital, and we emphasised the fact that Dr. Matthews said nothing as to the proportion of convalescents to total small-pox patients. We had very good reason for indicating this further flaw in his evidence. In the first place, there is a very general conviction that it is acute cases of small-pox, and not convalescents, that give rise to the diffusion of the infection from the hospitals in which the patients are aggregated. Secondly, in the celebrated Fulham case, which was thrashed out before a Royal Commission, it was shown that, notwithstanding the admission of large numbers of convalescent small-pox patients, there was no evidence of the diffusion of the infection to houses around; whereas directly the admission of acute cases commenced there were "manifestations of excessive small-pox in the neighbourhood." And thirdly, we noticed that Dr. Matthews himself took pains to explain in his report that from June 29th, when the Lower Hospital was opened for the fever patients, the hospital as a whole "was used simultaneously for the reception

of convalescent small-pox and fever patients." (The italics are ours). He also pointed out that of the 1563 small-pox patients in question no less than 1552 were transferred from the hospital ships to his hospital, and he emphasises the peculiarity of his patients by pointing out that they had a fatality-rate of 0.32, or only $\frac{1}{31}$ th of that for the ordinary small-pox patients in the ships, including deaths at "the convalescent hospital." Why Dr. Matthews should, therefore, now tell us that the argument as to convalescence is "simply a begging of the question" we cannot understand. Under any circumstances we trust that we have answered Dr. Matthews when he asks, Why should the "question of vaccination and convalescence be used as arguments" in the matter? and that we have shown that the points to which we have adverted are of such importance as probably to govern the whole question at issue. So long as we have so much positive evidence in exactly the opposite direction we cannot accept a single instance of negative evidence and incomplete data as affording "sufficient evidence" for assuming that the diffusion of small-pox through the air does not extend to a distance of 1000 ft."

PAYING PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL.

THE question of paying patients in general hospitals was distinctly advanced by the discussion at the annual meeting of the governors of the Great Northern Central Hospital, a report of which is published in another column of our present issue. Dr. Glover's motion—condemning the system adopted under which paying patients are attended gratuitously by the honorary staff and asserting that our voluntary hospitals are meant essentially for those who cannot pay—was not, indeed, carried, but it was significantly supported by independent governors and by the whole of the honorary staff that were present. It is understood that a very importunate canvass had been made by the committee, who only got 7 votes more than were given for Dr. Glover's motion. A motion by Mr. Burdett to throw the wards open to paying patients who might be attended by their own medical men received only 2 votes—those of the proposer, and the seconder, Dr. Potter. It was resented, too, rather warmly by the treasurer. The two points insisted on by Dr. Glover are unanswerable—first, that the hospital with its 155 beds is practically the only hospital in the midst of a population of between 300,000 and 400,000, and is too small for the demand of the classes for whom hospitals exist; and that therefore the appropriation of beds under such circumstances for patients who can pay or whose friends can pay for them is calculated to discourage subscriptions. The second point was that there was no precedent in any general hospital in London for placing paying patients on gratuitous terms under the care of the honorary staff. Mr. Burdett said that this was contradicted by the case quoted by Dr. Glover from THE LANCET of last week, in which a lady had been admitted into the wards of the Hospital for Women, Soho-square, to be attended by the honorary staff for a guinea a week against the testimony of her medical man. Though the committee have secured a majority at the annual meeting in favour of their new-fangled system, they cannot fail to see that it is distasteful to many of their subscribers and to their own honorary staff. It represents a new departure—an attempt to cater for another class than that for which hospitals exist. It will be time enough to undertake this new kind of business when they have met the wants of the really poor. It is pleasant to be able to say that in other respects the hospital is well managed and worthy of the support of charitable persons. In the out-patient department the numbers for 1894 were 25,083, being 1207 less than in the previous year. No doubt many were included in this number who should not be

hospital patients at all, but the reduction shows that the inquiry system in force has some effect.

EXPOSING AN INFECTIOUS PERSON IN THE STREETS.

AT Bow-street Police-court on Tuesday, Feb. 26th, Mr. W. E. Taylor of Kilburn was summoned before Mr. Vaughan by Dr. Allan, medical officer of health for the Strand district, to answer a complaint that, contrary to the provisions of the Public Health (London) Act, Sec. 68 (b), he had caused his servant while suffering from scarlet fever to walk from Kilburn to the office of the Metropolitan Asylums Board in Norfolk-street, Strand, on the evening of Saturday, Feb. 16th. After hearing the evidence of a clerk in the employ of the Asylums Board, who was in charge of the office when Mr. Taylor arrived with his servant, and of Dr. Stewart, of the South-Western Fever Hospital, the magistrate found the charge proved and inflicted a penalty of 40s. and costs.

OUR "GIDEON GRAYS."

THE rural practitioner's lot is, as we all know, a stern and, so far as emolument goes, a very inadequately rewarded one; but certainly he has his *revanche* at the hands of our best men of letters. In the few strokes of a master Sir Walter Scott introduces us to the country medical practitioner, than whom "no creature works harder or is more poorly requited, unless, perhaps, it may be his horse"—the type of a class "from whom," he adds, "Scotland reaps more benefit and to whom she is, perhaps, more ungrateful than to any other class of men, excepting her schoolmasters." Since "Gideon Gray" the world has had many portraits of the sagacious, skilful, self-reliant, courageous, and nobly philanthropic rural practitioner—none, however, that come so near that master-work as the "William Maclure" of the Rev. John Watson ("Ian Maclaren"). In a little volume of sketches of Scottish country life, a volume which in a few weeks has had a circulation of nearly 30,000 copies, he gives a series of singularly graphic pictures of the daily and nightly experience of this "doctor of the old school," and with true artistic instinct chooses the episodes which bring the virtues of the class most vividly into play. For dramatic power there are fewer finer situations in fiction than the night journey through the flood undertaken by Maclure and the eminent surgeon from Glasgow to perform laparotomy on a poor peasant woman, for whom a less scantily provided neighbour had subscribed to procure the intervention of the great expert. "Four times," we read, "they left the road and took their way over fields, twice they forced a passage through a slap in a dyke, thrice they used gaps in the paling which Maclure had made on his downward journey," until they reached the winter-swollen Tochty. "With the first plunge into the bed of the stream the water rose to the axles, and then it crept up to the shafts, so that Sir George [the surgeon, a fine character sketch of the late Sir G. B. Macleod of Glasgow] could feel it lapping in about his feet, while the dogcart began to quiver, and it seemed as if it was to be carried away by the mass of black water racing past beneath." The passage once made, thanks to Maclure's sturdy mare Jess, the cottage is reached and, not a minute too soon, the operation is begun, with a head unperturbed and a hand unshaken by the series of hair-breadth escapes just effected. The successful result and the noble generosity of Macleod, seconding that of Maclure, in the matter of the fee are told with a simple directness that implies a knowledge of similar occurrences in real life. Then, again, in illustration of the humour that coexists with his humanity and aids the practitioner in reconciling himself to his

stern lot, we would place Maclure's observations on the homœopathic medicine chest beside the most caustic remarks of Baillie Nicol Jarvie or Richie Moniplies. The doctor has been summoned by a dapper, self-sufficient stranger to attend his boy labouring under surfelt-colic, and has lost much valuable time in obeying the trivial call. "You see, Dr. Maclure," says the parental Hopps, "we're homœopathists, and I have my little chest here." "Let's see it"; and Maclure takes out the little bottles and reads the names. "Belladonna; did ye ever hear the like? Aconite; it covers a'. Nux vomica! What next! Weel, my mannie," he says to Hopps, "it's a fine ploy, and ye'll better gang on wi' the nux till it's dune, and gie him ony ither o' the sweeties he fancies." The character sketch of Maclure, however, culminates in the closing chapter, entitled "The Doctor's Last Journey," which for power and pathos surpasses anything recently given forth by the Scottish school of fiction. There is nothing in Barrie or Crockett to equal it, and the deathbed scene with the good doctor's incoherent wanderings back to his patients and to the more trying episodes of his dramatic career cannot be read with dry eyes. Such tributes as this of Mr. Watson to the heroism and nobility of which our "Gideon Grays" are the exemplars go far to compensate us for the unworthy success of "My Novel," in which the practitioner Squills is made ridiculous by his want of Latin, or for the more unworthy satire of "In a Children's Hospital" of the late Poet Laureate. The world is not slow to sift the grain from the chaff in contemporary literature, and apportion their respective places to the author who can recognise true merit under external roughness, and to him, on the other hand, who is so impressed by the shagginess of the outer coat as to have no thought for the noble heart that beats under it.

ELECTROCUTION.

IN connexion with the process of killing criminals by means of electricity—"electrocution"—our American brethren are becoming alive to the fact that a shock, or series of shocks, given to a man or an animal may produce all the appearances of death without actually causing death—that is to say, the animal may lie insensible for a time and yet recover. Hence the possibility that a criminal executed by the electrical discharge might not be killed, but might only be stunned by the shock administered. This fact seems to have been considered as a novelty on the other side of the Atlantic. Here it is a piece of information that has for a long time past been understood. It has been observed that persons stricken by lightning, and apparently dead, have recovered during blood-letting, and it is a well-known fact that some years ago a large dog was struck down with an electric shock derived from a Franklin battery in cascade; an operation was performed upon it while it was unconscious and apparently dead, and it afterwards made a good and rapid recovery—an illustration of a painless operation with electricity as a mode of producing anaesthesia. It is also known that the observer who recorded the above, in using electricity as a means for killing animals intended for food, saw so many signs of recovery from the stroke after what at first seemed to be death that he abandoned the use of electricity for the object he had in view. Of course, a mistake arising from this circumstance and occurring in a human subject condemned to death would be amongst the most calamitous brutalities even an uncivilised community could be guilty of. It might lead practically to burying a man alive. Dr. Gibbons, an American writer who does not appear to have studied the experiments that have been made in this country, has been making research on the matter, and has actually come to the conclusion "that more murderers have paid the penalty

for their misdeeds on the dissecting-table than in the electric chair." He considers that a murderer named Taylor, who was presumed to be executed by electricity, was alive when supposed to be dead, and adds that "during my years of practice I have had three cases of persons struck by lightning who were supposed to be dead. They showed all the symptoms of death. They were entirely unconscious, and the accepted signs of life were suspended; yet they revived." It is said also that he—Gibbons—gave a convict named Wilson the offer that he would be present at his execution, and that after the convict had suffered the penalty of the law in the electric chair he would make an attempt to bring him back to life; but the convict demurred, on the ground that he would not care to expiate his offence a second time in the event of the complete success of the resuscitation—a very natural demurrer. The questions here considered have excited a singular inquiry in America. It has been asked, If a man is sentenced to death by the electric chair, and after the current has been applied the medical man in attendance pronounces him dead, should his friends revive him through any method, does he regain his liberty, must he serve the rest of his time in prison, or, we would ask, must he be executed again? The answer to this question by the *New York Sun*, as quoted by the *New York Medical Journal* of Feb. 16th, is as follows: "The execution under the present law in this State is not completed until the doctors have performed a necropsy. In other words, the doctors are executioners. After they have cut up the criminal there is no doubt about his being dead." "This has an ugly sound," says our medical contemporary, "but who can demonstrate that the *Sun* is wrong?" We agree with our contemporary to a certain extent, for it would certainly be very wrong if members of our profession, engaged naturally and honourably in the art of saving life, were brought to be employed as the final executioners by the work of the scalpel on the dissecting-room table. It is time that the whole profession of America should raise its voice against a possibility so awful, so dangerous to civilisation in general, and to one of the noblest professions in particular.

CONVICTIONS FOR DRUNKENNESS.

UNDER the title, "Drunkenness (England and Wales)," a return has just been issued by the Home Office showing the number of convictions for offences under the several enactments against drunkenness committed in England and Wales during the year 1893. The aggregate number of these convictions shown in the return is 153,072, being in the proportion of 5 per 1000 of the population of England and Wales enumerated in 1891. It should be noted, however, that there are blank returns for the three boroughs of Newcastle-upon-Tyne, Barnstaple, and Carmarthen; no explanation of this omission is given in the return, although it appears impossible to assume that no conviction for drunkenness occurred during the year in any of these towns. It is well to bear in mind that local convictions for drunkenness do not necessarily bear any constant relation to the local prevalence of drunkenness, since police regulations and their administration, and even the action of magistrates, vary widely in different localities. It may, at the same time, not be without interest to point out the extremely wide variations between the proportions of these convictions in different parts of England and Wales. It may first be noted that while the convictions were equal to 5 per 1000 of the population in England, they were 7 per 1000 in Wales. Speaking generally, the main excess of convictions both in England and Wales occurred in the towns, and was not by any means invariably greatest in the largest towns. In the most thoroughly rural counties, such as Bedford, Berks, Buckingham, Cambridge, Essex, Hertford, Huntingdon,

Oxford, Somerset, Suffolk, Norfolk, Sussex, Westmorland, and Wilts, the convictions did not number 3 per 1000, and were in many cases under 2 per 1000. The county of Salop, also mainly rural, forms, however, a striking exception, as the proportion of convictions was 7 per 1000, and equal to the proportion in Wales, where the high rate appears to be due to the prevalence of drunkenness among the miners of South Wales, as the rate among the population of nearly half a million in Glamorganshire was no less than 12 per 1000, while in North Wales the proportion did not exceed 5 per 1000. When we come to examine the returns from the various boroughs and to calculate the proportions of convictions to the population, it is impossible not to be startled at the extent of the differences and to wonder whether these proportions give any real indications of the varying proportions of prevalent drunkenness, and if so, how such local variations are to be explained. The proportion of convictions was under 1 per 1000 in Norwich and Coventry, and under 2 per 1000 in Bradford, Colchester, Peterborough, Tiverton, Banbury, and Winchester. Within the Metropolitan Police District, having a population of more than 5,500,000, the convictions averaged 5 per 1000; while the proportions in the other largest towns were Liverpool, 14; Manchester and Salford, 11; Leeds, 4; Sheffield, 3; Bristol, 5; Leicester, 4; Nottingham, 5; and Sunderland, 7. The county of Durham shows among the miners a similar excess to that noticed in the case of Glamorganshire, the proportion being 14 per 1000, while in Hartlepool it was 15, and in the city of Durham 16. Among the smaller towns the following excessive proportions may be noted: Blackpool, 12; Bath, 11; Wakefield, 10; Berwick-upon-Tweed, 12; Grimsby, 11; and Tynemouth, 28. Exceptional mention should be made of Newcastle-under-Lyme, which is debited in the return with 4758 convictions in a population of only 18,452, equal to 264 convictions per 1000 of the population, a proportion fifty-three times greater than the mean proportion in England and Wales. If this remarkable record of convicted drunkenness is not the result of a misprint it would be interesting to have some other explanation of the startling figures.

DEATH UNDER CHLOROFORM.

A DEATH under chloroform occurred recently at St. Bartholomew's Hospital. We have been favoured with the following particulars by the house-surgeon in charge of the case. The patient, a man aged forty-three, but looking much older, was admitted into St. Bartholomew's Hospital on Jan. 23rd for treatment of retention of urine caused by a stricture of the urethra. His general condition was bad; he had phthisis, both apices being affected. To pass a catheter it became necessary to anaesthetise the patient. Ether being contra-indicated by the condition of his lungs, chloroform was selected as being the best anaesthetic for the case. He took the chloroform badly, coughing and struggling a good deal. These complications rendered it difficult to keep the patient fully under the anaesthetic, but beyond these circumstances nothing occurred, and no really alarming symptoms were present. During the ensuing week the patient's condition remained very unsatisfactory, his temperature ranging at night to 102° or 103° F. On Feb. 1st, further operative measures being deemed advisable, chloroform was again required. The anaesthetic was given on lint, half a drachm being poured on it from time to time. The lint was held about four inches from the face and approximated by degrees. The struggling stage was again severe and prolonged, and, to avoid too much vapour being inhaled, the lint was repeatedly removed from the face. In about ten minutes from the commencement of the inhalation, about three drachms and a half of chloroform having been poured upon the lint and the patient apparently just

"going under," the temporal pulse suddenly failed and the patient grew pale. Respiration continued quite regularly. No radial pulse was to be felt nor was the precordial beat perceptible. The breathing remained regular for some two minutes, when it grew slow and laboured. The pupil of the left eye never dilated (the right eye was affected with old iritis). The usual restorative measures failed to save the patient. The necropsy showed extreme fatty degeneration of the myocardium. Tubercle existed in the lungs and kidneys. The careful report before us seems to indicate that this patient died from cardiac failure, no doubt determined by the depressing effect upon the heart of the prolonged struggling and the anaesthetic. The influence of dyspnoea and the cough—i.e., violent expiratory effects upon a fatty and therefore weakened heart—can readily be gauged, even without the primary depression of circulation usual under chloroform, and these appear to have been the factors at work in this case.

REPORTERS IN HOSPITAL WARDS.

THE daily newspapers in Brussels having from time to time published accounts of hospital cases supplied to them by reporters who in their search for copy had managed to get into the wards and operating theatres, mingling with the students and hearing the remarks of the professor, a strong feeling has been aroused in professional circles that some steps should be taken to put a stop to unauthorised communications of this kind appearing in the lay press. A meeting was therefore held a short time ago of the members of the various hospital staffs, under the presidency of M. van Schoor, at which it was resolved that all non-medical persons should be forbidden to go round the wards with the physicians or surgeons. One of the speakers remarked that he had already frequently turned reporters out of his wards, that one must have the courage to do so always and to turn a deaf ear to their requests for information, and that he had, moreover, intimated to such of his students as were in the habit of adding to their resources by writing for the papers that if ever they dragged his name before the public he would take very good care that they should no longer have the privileges of medical students.

THE HISTORIC WINTERS OF EUROPE.

FOR the duration and severity of its wintry weather the year now passing stands out as an *annus mirabilis*. Among its predecessors similarly notable was 1402, when the Venetian lagoons were frozen over for many weeks, and 1441, when Lionel d'Este entertained on the frozen Po a numerous company of banqueters. In 1493 not only the Venetian lagoons, but the port of Genoa, were one mass of solid ice—a state of things repeated in 1503, when Marseilles Harbour was also frozen. In 1594-95 the Mediterranean was frozen at Marseilles, and the Adriatic at Venice, and on Jan. 23rd and 24th, 1665, the Arno at Florence was a racecourse bearing not only the competitors, but innumerable spectators. In 1657-58 nearly all the Italian rivers were flooded with ice, and Rome was well-nigh buried under snow, while in Sweden King Charles X. crossed the Little Belt on foot at the head of 20,000 soldiers, though at the close of the march the ice gave way and some squadrons of cavalry perished. The winter of 1705 was terribly severe, as was also that of 1709—the year of the battle of Poltava, when for three months all the European rivers were frozen over, as well as those of North America, and at Paris the thermometer sank to 23° below zero. In 1740 there was constructed at St. Petersburg a vast ice palace, in front of which was planted a park of artillery made of ice, which, charged with shot, pierced at sixty paces an axis of 54 millimetres. In 1776-77 all the Italian rivers were frozen—a state of things repeated with still more severity in

1789-89, when the deepest lakes were floored with thick ice, and the temperature from the south to the north of Europe descended from 20° to 40° below zero. Again, in 1794-95 the French cavalry, by a brilliant operation on the frozen Texel, captured the Dutch fleet. Similarly severe was 1798-99, the thermometer registering 17° below zero at Lodi. The winter of Napoleon's retreat from Moscow was *an annus mirabilis* for rigour; that of 1819-20 was remarkable for many successive weeks of unbroken frost, as was also that of 1829-30, so disastrous to agriculture. In the Alta Italia in 1844-45 sentinels on duty were frozen at their posts, while hardly less painfully memorable were 1849-50, 1853-54, and 1867-68. Few can have forgotten the terrible winter of 1870-71, from which all Europe suffered, notably the troops besieging and defending Paris. Long and rigorous was the frost of 1879-80—the thermometer marking at Piacenza 18° below zero. Very heavy and persistent snowfall characterised 1887-88, while between that and the present the most severe winter was undoubtedly that of 1890-91.

THE VALUE OF BACTERIOLOGICAL EXAMINATIONS IN DIPHTHERIA.

DR. THRESH in his annual report for 1894, which we hope to notice more fully later, draws attention to the danger of placing too much reliance upon the negative results of bacteriological examination in diphtheria. Although, as Dr. Thresh observes, the discovery of the diphtheritic bacilli is sufficient to establish the diagnosis, their non-discovery does not justify the declaration of the case from which the membrane or secretion was taken as not diphtheria. We have already drawn attention to this question in the columns of THE LANCET, and we are glad to see that Dr. Thresh has also been led, as a result of his experience, towards the same conclusion. As he remarks, the utility of this method of diagnosis is limited, as the examination of the throat may at one time show no bacilli, while at another some may be detected. The result, no doubt, depends in a measure upon the manipulative skill possessed by the observer who procures the specimen, but certainly it appears to us that negative evidence should only be acted upon after repeated examinations. To say this, however, is equivalent to depreciating in some degree the value of the method from the standpoint of the diagnostician, inasmuch as a busy practitioner can but ill afford the time necessary for collecting and despatching specimens of membrane. These remarks, however, in no wise militate against the great value of positive results or the importance of repeated bacteriological examination where practicable.

"PHRENOSIS PELLAGRÆ."

IN medico-psychological classification this term is peculiar to Italy, as the thing signified is almost exclusively Italian. It signifies the mental degeneration due to pellagra, that erythematous affection so common in the delta of the Po and due to the consumption of unsound maize. Hebetude resulting in absolute dementia represents the initiatory and the closing symptoms of the malady, though there are cases in which hallucination, prompting to eccentric and even violent, not to say lethal, acts, is the outcome of the progressive degeneration of the sensorium. A grave recrudescence of this disease is reported from Rovigo, and the Italian Government is actively subsidising the provincial council in combating it on the one hand and adopting prophylactic measures on the other. The houses in which the victims to the "frenosi pellagrosi" are under treatment are being reinforced in *personnel* and in the alimentary as well as therapeutic means of cure; while all the syndics (mayors) of the towns have received an official circular indicating the hygienic,

and especially the dietetic, *régime* to be applied to the peasantry of the affected or threatened districts. "Locande sanitarie" (sanitary stations) are established at the more severely visited centres, amply provided with wholesome, sustaining food, and in addition to these the "cucine economiche" (cheap kitchens) are open to all who can afford to avail themselves of the same, or to whom the charitably disposed have furnished tickets admitting to them. The water-supply—an important factor in combating pellagra, particularly in the marshy levels of the Polesine—is being attended to in the communes, and the dwellings of the labourers ("case coloniche") are periodically inspected and put in order. All this, be it noted, is inspired by the exacerbation of a malady epidemic in that region, and illustrates once more the fatal policy of so many southern provinces in waiting till the enemy is attacking in force instead of forestalling him by carrying the war into his camp.

SELF POISONING.

MAX NORDAU in his interesting work "Degeneration," says that the poisoning of civilised peoples continues to increase. He is referring chiefly to alcohol and tobacco; but, as a correspondent reminds us in a letter which will be found in another column, there is a widespread and dangerous tendency among the public, especially during an epidemic like the present, to fly to the indiscriminate use of drugs. We are sorry to see in a lay contemporary a summary of treatment, not only hygienic but therapeutical, culled from various sources. Dover's powder and salicylate of soda are mentioned, and no doubt these are valuable drugs when employed under medical supervision; but we wonder how many people after reading the article we refer to will take either or both on their own responsibility, possibly with serious results. Our object is not to deprecate therapeutic medication, but only to warn the average citizen that if he thinks he has influenza he should call in his medical man to prescribe for him and not dose himself. Dover's powder is poison, and the responsibility assumed by our contemporary in recommending to its numerous readers the use of the powder indiscriminately is very considerable. Another paper enjoying a well-deserved reputation has published the recipes of three London physicians against influenza. No doubt this was well meant; but it would have been, had the recipes been correctly given, a dangerous inducement to mischievous self-drugging. As the doses, however, are all wrong the advice gratis may prove especially pernicious.

THE PURIFICATION OF THE AIR BY SNOW.

AFTER the hardships we have endured through the late severe frost—which we trust is now a matter of history, though its demise would appear to be slow—it is pleasant to reflect that in some respects possibly there were influences for good at work. Thus, it seems that the snow which fell during the severe season was characterised by an unusual porosity and a regularity of crystalline form, indicating its formation in a calm atmosphere, which endowed it with distinct purifying powers upon the air through which it descended. That the imprisonment of suspended impurities in the air in the pores of the falling snow takes place is clear from the following analysis of a sample of melted snow collected on Jan. 30th last in the quadrangle of Somerset House. It contained in grains per gallon, according to Mr. John B. Coppock, F.C.S.: total solid matter, 17.32; mineral matter, 6.25; carbonaceous matter, 11.07; free ammonia, 4.65; and albuminoid ammonia, 6.50. It is suggested that these results would indicate the value of a fall of snow, not only from an agricultural point of view, but also from a hygienic standpoint. We may accept the former as probable, since

¹ Chemical News, Feb. 22nd, 1895.

and especially the dietetic, *rigine*, to be upon the penantry of the affected or threatened in "Locande sanitarie" (sanitary stations) are within the more severely visited centres, supply patients with wholesome, sustaining food, and in addition with the "caccine economiche" (cheap tickets) as all who can afford to avail themselves of it, or to whom the charitably disposed have tickets admitting to them. The water-supply is another factor in combating pellagra, particularly in the levels of the Polesine—is being attended to in the and the dwellings of the labourers ("case colonie") periodically inspected and put in order. All this, we are inspired by the exacerbation of a malady against the region, an illustration once more the fatal policy of southern provinces in waiting till the enemy's force instead of forestalling him by carrying the war camp.

SELF POISONING.

[illegible]

THE PURIFICATION OF THE AIR

THE PURIFICATION OF

AFTER the hardships we have endured this severe frost—which we trust is now a matter though its demise would appear to be slow—may reflect that in some respects possibly there may be for good at work. Thus, it seems that the country during the severe season was characterized by a formation and a regularity of crystalline form, porosity and a regularity of crystalline form, and a calm atmosphere, which upon the air distinct purifying powers upon the air have descended. That the improvement of the air in the air in the pores of the falling snow is clear from the following analysis of a sample collected on Jan. 30th last in the gateway of Hoone. It contained in grains per grain, John B. Coppock, F.C.S.: total solid matter, 6.55; carbonaceous matter, 11.65; matter, 6.25; and albuminoid matter, 4.65; and albuminoid matter, 4.65. These results would indicate the value of a soil from an agricultural point of view, but taken from a standpoint. We may accept the terms of the

J. Chemical News, Feb. 2nd 1880

obviously snow carries ammonia with it to the ground, where it may slightly enrich the soil, although it is to be observed that these nitrogenous impurities probably only exist in the impure air of towns; but, in regard to the latter hypothesis, we may reasonably, we think, entertain a doubt, inasmuch as the severe weather, accompanied as it was by heavy falls of snow, has unfortunately proved to be the forerunner of another serious outbreak of influenza and a decided increase in the mortality from diseases of the respiratory organs.

THE POWER OF THE ASSISTANT SANITARY INSPECTOR.

A CURIOUS, but not unimportant, case has just been decided by the magistrates of Portsmouth. It appears that on Dec. 15th, at about 9.30 in the evening, one of the assistant sanitary inspectors seized some meat exposed in a butcher's shop and took it to the medical officer of health for him to see before it was taken to a magistrate to be condemned. Whilst the medical officer of health was filling up the usual condemnation form the manager of the shop at which the meat had been seized took the meat from the cart and disappeared. The manager was subsequently prosecuted by the sanitary authority for impeding the assistant sanitary inspector in the execution of his duty. For the defence it was claimed by counsel that the meat was not lawfully in possession of the inspector, it having been proved that he was appointed by the authority as assistant sanitary inspector and not as an inspector of nuisances. The court adjourned for three weeks, and then gave a decision in favour of the defendant, holding that the assistant sanitary inspector had no power to seize. It appears from Section 189 of the Public Health Act that the sanitary authority has power to appoint only one inspector of nuisances, but may appoint as many assistants "as may be necessary and proper for the efficient execution of this Act" (Public Health Act, 1875). Should this decision be upheld in the higher courts it will seriously impede the inspection of meat, as an assistant-inspector may at any time be refused admission to slaughter-houses; and should such an assistant discover any meat exposed for sale he will seek the medical officer of health or inspector of nuisances instead of seizing the meat himself at once. Such a delay will give butchers ample opportunities to remove the meat, of which they will not be slow to take advantage.

THE CANAL BOATS ACTS.

In the twenty-third annual report of the Local Government Board, which has just been issued, will be found an interesting account by Mr. John Brydone, the inspector under the Acts, as to the condition of the canal boats during 1893. As an instance of the amount of work which a proper inspectorial control necessitates, Mr. Brydone mentions the case of one local inspector who saw but seven boats in the course of 119 visits to the waterways of his district, while two others are reported to have made no less than 68 and 138 visits respectively without encountering a single craft. It is satisfactory to note that Mr. Brydone has met with but few cases of overcrowding in the period under review ; and in reference to an inspection made by himself of the boats trading on the Medway he states that he was greatly pleased with the excellent condition of every one examined. Cases of infectious disease were apparently more numerous during 1893 than formerly, and they consisted of 18 cases of small-pox, 13 of scarlet fever, 10 of typhoid fever, 2 of diphtheria, and 1 of erysipelas. The coal strike imposed, Mr. Brydone states, great hardships on the boat population, as they had to maintain their horses as well as their families during the absence of work. In some districts it appears that boats were lying idle from

August to December. Mr. Brydone gives a list of the inspections made in the various districts and of the infringements of the Acts which were observed ; and he also gives an idea of the extent of the canal population by telling us that during 1893 there were 12,479 boats on the books of the registration authorities. In concluding his report Mr. Brydone affirms emphatically that the Acts continue to exert the most beneficial influence upon the boat population, and that they have operated in a high degree in reducing the number of women and children travelling with the boats. The women are, he reports, feeling more and more that the canal boat employment is not a fitting one for them, and that the cabin homes are not proper places for the rearing of young children.

THE BARKER ANATOMY PRIZES.

THE Royal College of Surgeons in Ireland offer two prizes of £26 5s. each, open to any student whose name is on the anatomical class-list of any school in the United Kingdom. The subjects for competition are two dissections—one of the kidneys, the other of the rectum—both as seen from behind, and prepared with a view to demonstrate the surgical relations of the organs, the exposure of the rectum having special relation to its removal by the trans-sacral method. The conditions of the competition may be obtained from Mr. J. Alfred Scott, M.D., F.R.C.S. Irel., Curator of the Museums, Royal College of Surgeons, Dublin.

PROFESSOR W. R. SMITH AND THE MEDICAL
SUPERINTENDENTS OF THE HOSPITALS OF
THE METROPOLITAN ASYLUMS BOARD.

In the *Times* of Monday, Feb. 4th, a brief report was published of a speech made by Professor W. R. Smith, M.D., at the meeting of the Metropolitan Asylums Board on Saturday, Feb. 2nd. It is there stated that Professor Smith concluded his remarks "by referring in strong terms of censure to the action of some of the medical superintendents of the board, who had communicated unofficial and unauthorised statistics to the leading medical journals." Being desirous of learning more particularly the circumstances which Professor Smith thus condemned, we wrote on Feb. 6th begging him to be so kind as to furnish us either with a copy of his remarks or a reference to any source where those remarks were fully and correctly reported, for we felt that if he were correctly reported Professor Smith had taken upon himself a task that sat exceedingly badly upon him in thus appearing as a sort of impeacher of his professional brethren, and we were anxious to give him an early opportunity of repudiating a wrong interpretation of his words. We received no reply, and the statement of the *Times* that Professor Smith had used "strong terms of censure" remained uncorrected. On Feb. 21st we again wrote to Professor Smith to remind him that so far he had not favoured us with any reply to our inquiry with reference to his speech, and on Feb. 27th we received a call from Professor Smith in reference to the matter. He then repudiated the word "censure" as applied to his remarks. This we are glad to learn, for it could obviously be no part of Professor Smith's duties to sit in judgment upon the attitudes of the medical superintendents of the hospitals under the jurisdiction of the Metropolitan Asylums Board. As a member of that board his public duties would make it necessary for him to take notice of any existent abuses. That is undoubted. But he must feel that it is no part of his duty to suggest the passing of votes of censure on his professional brethren, and we are glad to be able hereby to state that he did not intend to do so. We feel sure that Professor Smith, who himself fills several official posts, has no wish to add to the difficulties of other members of his

profession who are somewhat similarly circumstanced, or as an individual to usurp the functions of the Board, as would have appeared by the uncorrected report of his speech.

LORD ROSEBERY.

WE are glad to say that the Premier is now practically recovered from his attack of influenza, but the sleeplessness is still extreme, and so in some measure retards his progress to recovery. The attack has been from the first of an asthenic character, but not otherwise severe; there have been no complications. On Wednesday his lordship was able to see his private secretary for the first time since his illness and give him a few directions, but he is still quite unfit to transact any public business.

DIPHTHERIA IN LONDON.

DURING the two weeks ended last Saturday the deaths from diphtheria in London have maintained a steady decline on recent preceding weeks—namely, 27, or 4 below the corrected average, in the week ended Feb. 16th, against 29, 45, and 34 in the three weeks immediately precedent; followed by 29 last week, a number still below the corrected average by 2. Of the total of 56 deaths in the two weeks, 36 were in children aged from one to five years, this being 64 per cent. of the total. Of the 56, Poplar is credited with 6, as is also Camberwell, Greenwich with 5, St. Pancras and Battersea each with 4, Plumstead with 3, and Paddington, Islington, and Hackney each with 2 deaths. In Greater London in the fortnight there were 17 registered deaths from the disease, of which 8 belonged to West Ham and 2 each to Edmonton and Brentford districts.

"THE LAW'S DELAYS" IN VACCINATION.

IT has in time past been repeatedly, and with good reason, asserted that radical changes are called for in regard to the administration of the law of vaccination. One of the changes should assuredly be to vest local health bodies with the powers now vested in the guardians of the poor. An instance of the folly of the present system is recorded in the report of Dr. Wm. Brown, the health officer of the Stapleton urban district, as having occurred during the past year. Small-pox having been imported into the district, the patient was promptly removed to hospital on receipt of the certificate of notification. But meanwhile four persons resident in the invaded house had been exposed to the risk of the introduced infection, and the fact of their need of revaccination was accordingly at once made known to the Barton Regis Poor-law body as the "vaccination authority." Nevertheless, eight days later no action had been taken towards administering the needed prophylactic, because, forsooth, "it was not the month for vaccination." Dr. Brown hereupon himself, at his own cost, procured calf lymph and performed the operations, but too late to avert danger, as two of the four inmates contracted small-pox. Dr. Brown, like many another medical officer of health in like case, took upon him a duty imposed by law upon other authorities in his efforts to stay the spread of a disease by the best-known remedy, and one which could have been promptly administered in legal fashion by the officers of the board of guardians—it may be to the prevention, almost to certainty, of the two cases of small-pox which developed in the house. Ample powers are granted to Poor-law bodies for immediate action in emergent circumstances like the one in question; and the excuse for inaction which Dr. Brown chronicles only serves to exaggerate the neglect displayed. Only when the State remedies for the prevention and stay of disease are in the hands of the bodies charged with the function of safeguarding the public health can we hope to see prompt and efficient measures adopted. The need for prompt revaccination in such cases as

the above is often recognised by the sanitary authority which indemnifies the medical officer for carrying it out; and surely, if this be so, in time of epidemic it would naturally fall to the duty of the guardians of public health to supervise vaccination in general, as a potent safeguard to the community.

AN AMATEUR.

MISS MARGARET LUCY TYLER of Pymmes Park, Edmonton, is a fortunate woman. A baby of eighteen months being ill was confided to her untutored care; she prescribed for it and it died. We say that Miss Tyler is a fortunate woman, for although it appears that she meddled in the grossest way with what did not concern her, and with what she could not possibly understand, it does not appear that she actually gave the unfortunate child anything that could do it any harm. The evidence of the practitioner who had seen the child before it fell under Miss Tyler's medical care proved that the lady's prescriptions were harmless, and so saved her from an exceedingly awkward position; but we hope that the sad issue of the case will keep Miss Tyler from dabbling in medicine, lest her next appearance in a coroner's court be less agreeable to her.

THE DIFFUSION OF SMALL-POX.

SMALL-POX last week showed some disposition towards recrudescence in the metropolis, where 21 fresh cases were recorded, the major portion of them being, however, due to the renewed prevalence of the disease in the parish of Marylebone. The sanitary officials have been severely handicapped in that parish by the occurrence of cases in crowded localities and under circumstances which have put all their well-laid plans for dealing with the disease in the background, for the reason that occurrences have remained unnotified, and therefore unremoved, with consequent resulting danger to surrounding populations. The single death from small-pox in London last week was in an unvaccinated infant belonging to Marylebone. Elsewhere in the metropolis there is nothing to report of any moment. The removals to the institutions of the Metropolitan Asylums Board during the week numbered 19, against 21, 18, and 18 in the preceding three weeks; whilst at the close of the week the patients remaining under isolation were 75, the number having been steadily increasing since the week ended Dec. 22nd, when it was 15, four weeks later it was 32, and four weeks still later 67. In the remainder of the country the news is much more reassuring, there having been only a case or two at Birmingham and a few other midland towns, and three or four attacks and one death registered at Derby. In Lancashire we hear of a small invasion at Burnley and of a case or two at Liverpool; but the provinces just now appear to be fairly free from the disease. At Edinburgh some dozen cases have been reported in the second week of February. In Dublin in the same week some slight decrease in the admissions to hospital was manifested, these having fallen from 64, 69, and 60 in the preceding three weeks to 56, the discharge, however, showing no corresponding increase; whilst the patients left in hospital at the close of the week were 149 in number, in addition to 115 convalescents at Kilmainham, making a total of 264, a decline on previous totals. Of the 8 deaths in the week, 3 were in vaccinated and 3 in unvaccinated adults, no statement being forthcoming as to the condition as to vaccination of the remaining deceased persons.

THE next meeting of the Pathological Society of London will be devoted to a discussion upon the Bacteriology and Pathological Chemistry of Diphtheria and its Antitoxin. The subject will be introduced by Dr. Bertram Hunt. Several

the above is often recognised by the sanitary authorities, and indemnifies the medical officer for carrying out his duty. If this be so, in time of epidemic it would naturally be the duty of the guardians of public health to suppress vaccination in general, as a potent safeguard to the community.

AN AMATEUR.

MISS MARGARET LUCY TYLER, of Pymme Park, is a fortunate woman. A baby of eighteen months was confined to her untutored care; the practitioner was called in, and the child died. We say that Miss Tyler is a fortunate woman, although it appears that she meddled in the process of what did not concern her, and with what she was not ably to understand, it does not appear that she was any unfortunate child anything that could do it any harm. The evidence of the practitioner who had seen the child fall under Miss Tyler's medical care proved that the prescriptions were harmless, and so proved to be an exceedingly awkward position; but we have no issue of the case will keep Miss Tyler from any medicine, lest her next appearance in a court be less agreeable to her.

THE DIFFUSION OF SMALL-POX

THE DIFFUSION OF SMALL-POX

SMALL-POX last week showed some disposition to recrudescence in the metropolis, where 21 fresh cases were recorded, the major portion of them being those of the renewed prevalence of the disease in the Marylebone. The sanitary officials have been handicapped in that parish by the occurrence in crowded localities and under circumstances in which it was difficult to have put all their well-laid plans for the suppression of the disease in the background, for the small occurrences have remained unnoticed, and have been removed, with consequent resulting large numbers of unvaccinated persons, and the disease has been spreading in the populations. The single death from small-pox last week was in an unvaccinated infant, aged 18 months, who died in the Marylebone. Elsewhere in the metropolis there was no report of any moment. The removals to the Metropolitan Asylums Board during the week were 19, against 21, 18, and 18 in the preceding weeks, whilst at the close of the week the number under isolation were 75, the number having increased since the week ended Dec. 21st, 1894, by 15, four weeks later it was 32, and still later 67. In the remainder of the country is much more reassuring, there having been only two or three at Birmingham and a few deaths at three or four attacks and one death at three. In Lancashire we hear of a small increase in the number of cases or two at Liverpool; but the province appears to be fairly free from the disease. In the other counties we have reported in the last week several cases have been reported in the same way in February. In Dublin in the same week the increase in the admissions to hospital was reported having fallen from 64, 69, and 60 in the preceding weeks to 56, the discharge, however, showed an increase; the patients left in hospital at the close of the week were 149 in number, in addition to 10 at Kilmarnock, making a total of 159, a decrease of 3 in unvaccinated adults, no statement being made as to the condition as to vaccination of the deceased persons.

...ing of the Pathological Society ...
...ion upon ...

THE next meeting of the Pathological Society will be devoted to a discussion upon the Pathological Chemistry of Diphtheria and the subject will be introduced by Dr. Brown.

members of the society who have been working at the subject have promised to take part in the discussion.

At a meeting of the council of the Mason Science College, Birmingham, on Feb. 23rd, Mr. Oliver Pemberton, F.R.C.S. Eng., was for the third year elected President.

Pharmacology and Therapeutics.

A RETROSPECT.

THE therapeutics of the past year are remarkable for the enormous extension of serum therapeutics—i.e., the therapeutic use of bacterial products—and also for the increase of organic extracts. Perhaps, after all, our ancestors were not so very far out when they filled their books on natural history with long accounts of the medicines to be derived from various animals. To this day, in the peninsula of Athos, oil in which a new-born rat has been macerated to solution is esteemed a sovereign remedy for all pains; while in Russia tinctures prepared from toads and cockroaches are used by the peasantry with apparent success in the treatment of cardiac ascites and œdema. The list of coal-tar derivatives still lengthens, and in the new Year-book of Treatment we find eight new preparations.

A NEW MANUAL OF PRESCRIPTION.

America has long been famed for the "elegance" of her pharmaceutical preparations, and it should be the aim of every practitioner to make his prescriptions pleasant as well as scientific. A new Manual of Prescription Writing, published in Philadelphia, gives a number of wise cautions to the prescription writer. A number of prescriptions are given to instance incompatibles and a full dosage table is given in both metric and ordinary systems of measures and weights.

PATENT MEDICINES.

In the February number of the *Druggists' Circular*, a trade journal published in New York, there is an admirable little article upon a Bill recently introduced into the Lower House of the Alabama Legislature. This Bill makes it unlawful to sell or give away any patent or proprietary medicine unless the formula of such medicine is shown on the label of the packet containing the same. The *Druggists' Circular* does not seem to have much expectation of this Bill passing, but its introduction is a good sign of a more healthy feeling prevailing as to nostrums. The old adage, however, we suppose will still hold good, "Populus vult decipi, et decipitur," and if a similar Bill were introduced in this country we suppose there would be the same doubts as to its success. We have no intention of giving the proprietors of quack medicines gratuitous advertisement, but we do not think it right that the people of this country, "mostly fools" though they may be, should be given the opportunity of letting diseases run on till they get too far advanced for even relief, while they waste valuable time in buying and using aloes pills, yellow oxide of mercury ointment, iodide of potassium, and sarsaparilla or "electricity" at some 800 per cent. over cost price. The way in which religious papers advertise these wares is disgraceful, and so-called cures are generally certified by ministers of religion as being due to the effects of Podger's Pills or Hookey's Elixir. In a good many instances patent medicines are harmless, but there are two notable exceptions, chlorodyne and neuraline. The former is undoubtedly a very valuable preparation, and very dangerous if taken recklessly. It contains at least three most powerful poisons, and yet there is absolutely nothing to prevent anyone, however ignorant, from buying as much as he likes, while, were he to try to purchase the ingredients separately, the illogical Legislature would step in and prevent him. Neuraline contains, we believe, aconitine, perhaps the most virulent poison known, and the sale of this is safeguarded by no restriction whatever. As long as this kind of thing can go on the Sale of Poisons Act is simply useless.

HÆMOSTATICS.

A correspondent from Cannes informs us that he has tried with great success a new haemostatic—ferripyrrin—a compound of chloride of iron and antipyrin which has the great advantage of being non-caustic. He found that pro-

longed application by means of tampons left only a slight anæsthesia of the mucous membrane. The hæmostatic properties of antipyrin have also been made use of in uterine hæmorrhages by Dr. Labadie-Lagrave of l'Hôpital de la Maternité, Paris. The method used, as described by *La Revue Médicale* is as follows:—Equal parts of salt- and antipyrin are put into a tube and heated over a spirit lamp. The mixture soon melts into a liquid of a slight brownish colour, but must not be yet used, as at this stage it again rapidly solidifies, but heat must be continued until the colour is a pronounced brown. When this stage is reached the mixture is introduced into the uterus by means of cotton-wool on probes (care being taken that the liquid is not applied too hot). One or two applications are then made according to the severity of the hæmorrhage, which is said usually to cease very quickly. The operation is simple and free from danger, and has proved useful in cases of fungating endometritis, fibromyomata, and other tumours.

THE THERAPEUTIC USES OF STRONTIUM.

The *Tribune Médicale* in discussing the treatment of convulsions recommends strontium bromide internally. This salt, which is very soluble in water, has also been given instead of potassium bromide in epilepsy, in some cases of which it is better borne over a long period than the potassium salt. It has also been given in cases of dilated stomach with some success. The dose is five to thirty grains. The lactate of strontium has been found serviceable in checking albuminuria in cases of parenchymatous nephritis, but is said to be of no use in the interstitial variety.¹ Wood² found that strontium bromide was less prone than the potassium salt to produce acne and other disagreeable symptoms, but that it also had less control over the epileptic paroxysm.

THE ESSENTIAL OILS OF THE BRITISH PHARMACOPEIA.

In connexion with the proposed revision of the Pharmacopœia we have received a copy of a *brochure* by Mr. Helbing and Dr. Passmore, which contains the results of their experience of a large number of essential oils, from which they have been able to define the limits of variation in genuine oils of good quality. The results appear to be based for the most part upon physical tests, boiling points, freezing points, optical activity, &c. The chemical method recently suggested for standardising eucalyptus oil, depending upon the formation of eucalyptol phosphate on the addition of syrupy phosphoric acid, is not viewed with favour, and it is remarked that the method of fractional distillation is preferable and affords constant results. Some twenty types of essential oils are dealt with, each section concluding with practical suggestions bearing upon future pharmacopœial requirements. The essential oils belong, of course, to an important group of bodies in the Pharmacopœia, and there is little doubt that they have frequently been the subject of considerable adulteration, especially as the means of detection is not easily or conveniently carried out. The value of this contribution is therefore obvious, and the results are such as to merit the careful attention of those who are about to consider the much-needed revision of the British Pharmacopœia.

THE TREATMENT OF DYSENTERY.

Surgeon-Major S. T. Aretoon, of the 1st Baluch Battalion, L.I., sends us the following communication:—"I wish to bring to the notice of the profession a new treatment for acute dysentery. It is not original, but was obtained from a medical work in Persian. This is what the book stated (I translate):—"Treatment for acute dysentery: Reduce cinnamon bark to a fine powder, take one and a half drachms, mix it with a little "mullai" (the cream which gathers on the top of boiled milk after it is allowed to settle and cool), and administer in the morning on an empty stomach. The patient will be cured.' I have made a slight alteration in the above. The powdered cinnamon is given in drachm doses only, mixed with a few drops of water and made into a ball, which is given to the patient to eat, washed down by a mouthful or two of water. This quantity is repeated again in the evening, and so on, morning and evening, until a cure is effected. It is a little over two years since I started this method of treatment, and have cured about thirty cases of the disease. Often patients have been cured by only one or two doses of the drug, while my worst case was cured after five doses only, but a sixth was given to make quite sure. This method of treatment is vastly superior to

¹ Germain Sée and others.

² Therapeutics: Smith, Elder & Co., London, 1894.

the ordinary ipecacuanha treatment in that the medicine is pleasant to take and causes no nausea or vomiting, and acts, if anything, quicker and better than ipecacuanha. If the drug were given in drachm and a half doses as recommended in the book, most probably cures would be effected more quickly, but my method has been quite quick enough. The earlier the treatment is begun the quicker the cure."

THE LOCAL GOVERNMENT BOARD REPORT (1893-94) ON FOOD AND WATER-SUPPLY.

IN view of the unfinished labours of the Select Parliamentary Committee on Food Products Adulteration—which will probably soon be reappointed now that Parliament has met again—the section of the report of the Local Government Board relating to the working of the Food and Drugs Act possesses more than ordinary interest. At the outset it may be stated that the present Blue-book shows distinctly that very little improvement has been effected in this section of State administration since the issue of the last Blue-book. Indeed, there is a remarkable analogy in the conclusions between the reports of this and the last official year. Thus in the 1892-93 Blue-book we read that the extent to which the Acts were utilised varied considerably, while they were absolutely ignored in four administrative counties and twenty-seven boroughs, and in other districts with the population ranging from 299,000 to 88,000 the number of samples taken for analysis varied from 35 to 8. The Board expressed surprise in 1893 that "the local authorities were content to leave the inhabitants without that protection against fraud by the sale of adulterated food which the exercise of the statutory powers conferred on the authority would be likely to ensure. So in the present report we read that within the jurisdiction of the County Councils of Hereford and Montgomery, and of the town councils of sixteen boroughs not one sample was taken for analysis during the year, while in the jurisdiction of nine other county councils and in eighteen other boroughs, including largely populated districts, the number of samples taken "was so small as obviously to afford no security against adulteration." And yet it happens that 37,233 samples were examined this year against 29,028 last year, the result of this slight increase being to show an increase of adulteration by 0.5 per cent. This is one point surely which is worthy the notice of the Food Products Adulteration Committee. In a table in the appendix we find that whereas 240 samples were taken in a certain district, the result showing an adulteration of 26 per cent., in the district of an adjoining vestry, returning below 9 per cent. of adulteration, only twenty-four samples during the year were taken. It might well happen, therefore, that the administration of the Act is efficient at one end of a street and not at the other, or even on the one side and not on the other. This is not only against the interests of the public, but unfair to tradesmen. The inadequacy of fines and the leniency of magistrates formed another subject of comment in last year's Blue-book, and still we read in the report before us that "the fact remains that in the majority of cases the fine has not been sufficient to deter a dishonest dealer from repeating his offence." Here is another point which should receive the attention of those who are called upon to effect reform where it may be necessary. No article of food requires more careful consideration, perhaps, than milk, which, "as usual, formed the chief subject of analysis" during the past year, and out of 15,543 samples analysed no less than 2310, or 14.9 per cent., were reported against. With the exception of spirits, the extent of adulteration of which (chiefly with water) was 19.7 per cent., milk proved to be the article most extensively sophisticated. As, however, numbers of samples are reported as "poor," "very poor," "of doubtful genuineness," "probably slightly watered," it is probable that even this large proportion does not adequately represent the full extent of adulteration. With the view of placing the detection of watered milk on a more satisfactory basis Dr. Bell has made a great number of analyses, which included the milk of 273 individual cows and the mixed milk of fifty-five dairies. The results apparently show that while there has been a sensible improvement in the quality of milk since a previous investi-

gation ten years ago, as regards the proportion of fat, the non-fatty solids are in substantial agreement with the results obtained from the samples previously analysed. This improvement, we suggest, is not improbably due to improved methods of analysis for the more complete extraction of fat. An important observation is made in regard to the sale of milk on Sundays, on which day it is more frequently found to be watered than on week days, while again the milk supplied by contract to various large institutions is in many instances grossly adulterated. This attempt to evade the Act should be narrowly watched by the governing bodies of such institutions. Next to milk butter appears to be the subject of considerable adulteration (with water or foreign fat), the proportion of adulteration being 13.7 per cent., and in London, as in previous years, it is nearly twice as high as in the country. The adulteration of coffee has decreased sensibly; while in regard to other articles there is little important change to report except in the case of beer, the adulteration of which has diminished from 16.8 to 4.4, and in drugs from 20.4 to 11.3 per cent. Lastly, it appears that of the samples purchased privately 27 per cent. were reported against, or more than double the proportion of those purchased officially. This difference may be due to the fact that private purchasers will not incur the expense of analysis unless they have *prima facie* grounds for suspecting adulteration. At any rate, this is another fact which can scarcely escape the attention of those who may be led to recommend the revision of the Acts, especially in regard to the present system of inspection and the purchase of samples.

The recent Blue-book shows, therefore, that the defects of the present Act, in spite of having been indicated with emphasis from time to time in the Local Government Board reports, still exist; while it is important to observe that as the result of submitting a greater number of samples for analysis last year a higher percentage of adulteration has been reported.

Perhaps one of the most important statements contained in the Blue-book of 1893-94 in regard to water-supply is that relating to the quantity of water abstracted from the Thames by the metropolitan companies. It appears that the daily discharge of the Thames, including the amount withdrawn for water-supply, averages about 1,300,000,000 gallons, and that the maximum amount of water which the companies are collectively empowered to withdraw in twenty-four hours is 130,000,000 gallons, and from this it is concluded that the water daily extracted from the Thames for the use of the metropolis "is but a small fraction of the average amount of water discharged by the river." It must be remembered, however, that the quantity of water passing over Teddington weir varies enormously at different seasons. Thus, while in February, 1893, the average daily discharge was 3021.4 million gallons, the daily figures for September, 1893, averaged only 298.3 million gallons; while the lowest gauging occurred on Aug. 21st, when only 141.3 million gallons passed over the weir and 110 million gallons—nearly a half of the total flow—were abstracted for water-supply before reaching the weir. It was this fact which led the engineer of the London County Council to remark in a report¹ drawn up by him in 1891 that "it would be most dangerous to abstract any larger quantity." With regard to the quality of the Metropolitan water-supply, Professor Frankland's figures show that the Thames water distributed during the year 1893 was of a much better average quality than that sent out during the previous two years, although "it still fell short of that supplied during 1886 to 1890 inclusive." Speaking generally, the Lea water is superior to that of the Thames and the water in the upper reaches of the Lea is purer than that in the lower; but on the other hand it was found that the Lea water at the East London intakes contained twice as many bacteria as the Thames intakes, so that obviously the chemical quality of water is quite another thing from its bacterial quality. Professor Frankland's remarks upon the purifying influences of flow, insolation, efficient sand filtration, and of storage are in substantial accord with the conclusions contained in the report of the Royal Commission on Metropolitan Water-supply.² "It is gratifying to find," he says, "as the result of recent researches that the zymotic poisons are rapidly destroyed in running water exposed to sunlight, so that the most minute microscopic inspection of the water at the intakes of the various companies has hitherto failed to discover a single

¹ THE LANCET, Dec. 12th, 1891.

² THE LANCET, Sept. 30th, 1893.

boats. So far as invalids are concerned, the only route remaining that could be recommended was the second or eleven o'clock day service, when the passage could be effected in the big ships. Troubles, however, did not end here. Some weeks ago a very violent storm entirely destroyed the head of the eastern pier of Calais and carried away the lighthouse. Consequently, when the *Empress* was entering during a violent easterly gale an exceptionally large wave dashed her against the western pier, which in its turn was considerably damaged. It will be remembered that the *Empress* had one of her paddles smashed and was thrown on the sands, where her passengers in due course landed safe and sound. This has led to yet another restriction. The big ships are now not only withdrawn from all service after sunset, but they must no longer attempt to cross when there are easterly gales.

blowing, as the broken end of the eastern pier at Calais no longer affords sufficient protection. Nor is this all; some fishermen tried to bring into port an abandoned sailing-vessel, with the result that she was wrecked on the broken stump of the eastern pier. In a little while the wreck, beaten by heavy seas, snapped in two, and one half of the ship rolled over into the harbour entrance between the two jetties. The navigable space remaining was so narrow that the service of the big Channel steamers had to be abandoned altogether, no matter how favourable the weather might be. Fortunately the wreck has now been blown up with melinite, and the big ships are once more carrying passengers across.

From all this it will be seen that when advising patients how to cross, with the least possible exposure, the eleven o'clock day route can alone be recommended, and this only when there is no prospect of an easterly gale. For invalids such restrictions are really very serious. So far as the hale and strong are concerned the dangerous condition of the entrance of Calais Harbour need not be a matter of much concern. There are no rocks near Calais, and apparently the worst that can happen is that the ship might be stranded upon the soft sands and the passengers made to wait till the tide has gone down so as to land over the ship's side. Such an experience, however, while only constituting an exciting adventure to a vigorous traveller, might have very serious consequences for an invalid. It is therefore most urgent, not only from the general point of view, but more especially with respect to the many thousand patients who are yearly sent to winter abroad, that the entrance of Calais Harbour should not be allowed to remain in its present condition.

Of course, the vast harbour works, on which so much labour and money have been expended, include a new and better entrance; only this is the portion of the scheme which, instead of being first taken in hand, has been left to the very last. The eastern jetty is to be demolished and a new jetty built in its stead. The entrance will then be 430 ft. instead of 328 ft. wide. But, what is more important, the foundations of the new jetty will be perpendicular, with the woodwork on the inner side of the harbour. Ships will therefore be able to come up along side of the jetty without the fear of grounding upon its foundations. Further, the jetty, instead of running parallel with the western jetty, will widen out like a sleeve, thus facilitating the manœuvres of ships entering. Of this new jetty the foundations of the first half, that nearest to the shore, are completed, and the upper or wooden part is finished for only a quarter of the total length. For the remainder thirteen metallic caissons have to be sunk under water in the sands, which will then be filled with masonry and constitute the foundations. Eight of these caissons are already in position; but the thirteenth, which is double the size of the others and will serve as the foundation of the new pierhead, is by far the most important and difficult to place. It has been ready since last September; but, as a fortnight's fine weather is necessary to sink it in the sands, it has been impossible, as yet, to attempt the operation, and a favourable opportunity is scarcely likely to occur before May or June next.

Altogether, the new jetty will not be completed and the foundations of the old jetty dug up and cleared away for about another two years. Happily, so far as the running of the larger steamers between Calais and Dover is concerned, the completion of these works is not necessary. The entrance to the harbour will be safe for the largest Channel passenger steamers when protection from the easterly winds and waves is secured by the construction of the foundations of the new pierhead, and when the entrance is widened by the removal of the foundations of the old and broken pierhead. The remains of the old jetty will then serve as an effective protection till the whole of the new pier is constructed. It is thought that this much at least of the works will be done by next autumn. Patients returning to England next spring will have to suffer from existing inconveniences, but no effort should be spared to secure a safe entrance in all weathers into Calais Harbour for the big steamers, who will convey patients travelling south at the end of this year. By dealing with the two pierheads, the old and the new—removing the one, building the other—this security can be ensured, and the work can easily be done during the summer if sufficient energy and determination are displayed. The reputation and the material interests of the town of Calais largely depend on the successful fulfilment of this task.

MASON COLLEGE ANNUAL DINNER.

THE annual dinner in commemoration of the founder of Mason College (who was born on Feb. 23rd, 1795) took place on Saturday night, at the Great Western Hotel, Birmingham. Professor Clifford Allbutt, M.D., F.R.C.P., F.R.S., Regius Professor of Physic in the University of Cambridge, presided over a large gathering, which included the Mayor (Alderman Fallows), Sir Walter Foster, M.P., Mr. Oliver Pemberton (President of the College), Dr. J. Gibbs (Vice-President), and the other trustees; the Principal (Dr. R. S. Heath), the Dean (Dr. Windle), and the members of the College staff; and about forty medical men from Birmingham and the midland counties.

The loyal toasts having been honoured, "The Memory of the Founder" was drunk in silence.

The Chairman, in proposing "The College," spoke of the munificence of wealthy men who in the past had founded such colleges as theirs, and, in alluding to Sir Josiah Mason, said he considered him a very remarkable man, for the reason that he not merely devoted large sums of money to very interesting and useful purposes, but in the development of those schemes he followed the advice of others as well as his own opinion. He was not in any way wedded to the primary and original scheme upon which he founded the college, and he enlarged the scheme twice in the life of the college after its original foundation. In the first instance, he understood that Sir Josiah Mason's idea was that the college should be limited to the giving of a rather narrow technical education; that he thought, and thought quite rightly, that there was very great need for that kind of education in certain crafts. He, however, soon seemed to recognise the advisability of putting into the work a spirit of a broader kind, and consequently he developed the college and brought it under the terms of a university college. He (the chairman) ventured to suggest, although to give degrees was a matter of legitimate ambition, that they might call Mason College a university college independently of it. The giving of degrees was not really a definite mark of a university college; it was, he thought, a secondary matter entirely. He deprecated the idea of degrees being given because of their commercial value, and said they should only be regarded by their possessors as indicating a good and useful training. He considered it rather an advantage that a college such as the Mason College and those of Yorkshire, Lancashire, and Manchester, placed as they were, should have begun as technical schools. It was sometimes said the character of the teaching in a technical college must be something baser than that which began in large and abstract studies. But that was a point of view which was very much weaker than formerly, one from which he absolutely dissented, and one which those colleges in the provinces were strong witnesses against. They could not teach anything in general unless they began by teaching something in particular, and he did not think it mattered what they taught so long as it was taught in a university spirit. Touching upon the subject of degrees, the chairman deprecated their use as advertisements, and said they merely signified two things. They signified the grade of an interior function within the university, and, therefore, were a matter of internal convenience; and also indicated that the teaching in the school where they were given was free, and so long as their students had to be examined by somebody else their teaching was not free. To have to cut and dry a Birmingham examination to please a London examiner, or a Liverpool examination to please a Cambridge set of examiners, was fatal to anything like variety and freedom within the walls of those colleges themselves. Therefore he hoped on their own behalf most sincerely that the time would come when Mason College would be able to give degrees, not because they wanted them for advertisement, but because they wanted to indicate the kind of training to which their own people had been put. They might place the work of a college of this kind in three stages: first for adapting a man for the duties he had to perform; then to go on to a wider knowledge, to general cultivation of the mind; and, thirdly, the ideal that they might pursue knowledge entirely for its own sake—what Milton called "for the contemplation of the sweet countenance of truth," and that he would call illumination. If they got those three degrees, in fact, then he did not care much when the time came for getting nominal degrees, except that it would free them to give their teaching in the best way they could.

MASON COLLEGE ANNUAL DINNER

THE annual dinner in commemoration of the late Mason College (who was born on Feb. 23rd, 1786, and died on Saturday night, at the Great Western Hotel, London) was held on Saturday night, at the Great Western Hotel, London. Professor Clifford Allbutt, M.D., F.R.C.P., F.R.S., was the guest of honor, and was accompanied by a large gathering, which included the Mayor (Mr. Walter Foster, M.P.), Sir Walter Foster, M.P., Mr. Oliver Pemberton, President of the College, Dr. J. Gibbs (Vice-President), the other trustees; the Principal (Dr. R. S. Hutt), and the members of the College and about forty medical men from Birmingham and its counties.

The loyal toasts having been honored, "The late Founder" was drunk in silence.

The Chairman, in proposing "The College," paid tribute to the munificence of wealthy men who in the past had founded such colleges as theirs, and, in alluding to Sir Josiah Mason, said he considered him a very remarkable man, for that he not merely devoted large sums of money to interesting and useful purposes, but in the execution of those schemes he followed the advice of as well as his own opinion. He was not a mere benefactor, but a founder of the primary and original scheme, and he enlarged the college, and he enlarged the scheme. In the life of the college after its original foundation, in its instance, he understood that Sir Josiah Mason's idea of the college should be limited to the giving of a medical technical education; that he thought, and that he thought, that there was very great need for this education in certain crafts. He, however, soon recognised the advisability of putting into the hands of a broader kind, and consequently he developed it, and brought it under the terms of a university (the chairman) ventured to suggest, although it was a matter of legitimate ambition, that they should make Mason College a university college independent of the University of London, and not really a department.

Principal Heath, in responding, observed that they owed a great debt of gratitude to the universities, but the problem they had to face in a busy city like Birmingham was different *totò cœlo* from that of the ancient universities. They were in the middle of great industrial enterprise, and the training they had to give had to bear relationship to that industry. The quality of breadwinning demanded a great deal more serious attention from them than it did from the University of Oxford or Cambridge. At the same time, they had had pointed out to them how technical education was not inconsistent with a liberal education, and how a lofty ideal and a high plane of intelligence were necessary and also attainable, although their training had to bear close relationship to the practical issues of life. They had great cause for gratitude in having received considerable sums during the year from generous friends. In that respect the year had been a favourable contrast to many years that had preceded it. They had received this year no less a sum than £17,000. The late Alderman Avery left them by will £2000, and just recently that had been supplemented by a gift of £2000 from the executors of his estate. An endowment of £5000 for the maintenance of the physical laboratory had also been anonymously contributed during the year. To endow the new department of education for elementary teachers Mr. George Kenrick had conveyed to the council securities producing an income of £200 a year, and that had been supplemented by a further gift from Mr. George Dixon, M.P., of £1000 for the same purpose. Lastly, Mr. John Corbett of Droitwich had founded scholarships with a capital sum of £1000, to bear his name. That was very encouraging, and it was to be hoped that a tide had set in in their favour that would lead them on to fortune.

Professor Windle also replied. He said that in Birmingham they had nothing to complain of with respect to the clinical field provided for the students. In addition to the General and Queen's Hospitals, at which the ordinary course of instruction was followed, students were able to attend the Fever Hospital and Lunatic Asylum, which were corporation institutions, and also by the kindness of their staffs the Eye, Orthopædic, and Ear and Throat Hospitals, at which they were able to follow some of the more important special branches of the profession. Nor had Birmingham anything to complain of in the medical school. It provided at present more than 50 per cent. of the honorary and paid staffs of the hospitals, a fact which was an eloquent vote of confidence in the school on the part of the managers of those institutions. The presence of medical students, moreover, at the hospitals had a very important bearing on the prosperity, of those institutions. He thought it was hardly recognised what a difference it would make to the managers if there were no medical students in the city, and if the work which they gratuitously performed in the hospitals had to be carried out by paid officers.

Professor Lapworth proposed "The City," to which the Mayor responded.

Professor Barling gave the toast of "The Visitors."

Sir Walter Foster, M.P., in response, spoke of the educational facilities of Birmingham, which had been largely brought about by the munificence of its citizens. He trusted that the example set would be followed by others, for there was nothing a man could do better than distribute his wealth while he lived. He was glad to know that in Birmingham one of its foremost citizens had founded an institution by which a child could climb to the highest position of culture and learning, and having that heritage the need for leaving him piles of wealth was taken away. Referring to the medical school, from his position on the General Medical Council he was able to say that the high standard of passes for which the Birmingham Medical School had always been distinguished was maintained, and more than maintained. Although no longer directly connected with the school he was still deeply interested in its prosperity.

Mr. Oliver Pemberton, in submitting "The Chairman," said in him they had one of the most brilliant examples of the union of science with the practice of medicine.

The Chairman briefly replied, and the proceedings terminated.

AN APPEAL.

WE have received the following letter from Mr. Henry Morris. It has reference to a sad case which we also desire to urge upon our readers as an exceedingly deserving one. We have been able to be of some temporary service, but some

time must elapse before the bread-winner, struck down so sadly while employed in charity, is in a condition, if ever, to earn his living again, and during that time help is and will be urgently needed. We desire to supplement Mr. Henry Morris's generous appeal.

"SIRS,—I hear that the merit of this case is known to yourselves, but I desire to make it known also to the profession through your columns.

"Charles Bryan Townshend, L.R.C.P., L.R.C.S. Irel., aged forty-two, was until recently in practice in King's-road, Chelsea. The work was hard, the patients poor, and bad debts prevented him from saving. His health requiring a change from Chelsea he sold his practice as a going concern of £500 a year and with the proceeds of the sale started in practice in Richmond-road, Kingston. In April, 1891, in attending a poor woman—a gratuitous patient—in her confinement he became inoculated with syphilis on the forefinger of the right hand. He did not realise the nature of the sore, and had no general treatment until he came under my charge in June, 1891. He then underwent a prolonged specific treatment. Shortly after Christmas last he became affected with spinal disease. For this I recommended him to consult Dr. Buzzard, which he did. Mr. Townshend is now seriously ill with complete paraplegia. He is a married man, with six children between the ages of ten and eighteen years. He had formed a nucleus of practice at Kingston, but by his present illness, which quite incapacitates him, he and his family are entirely deprived of any means of subsistence. Neither Mr. Townshend nor his wife, who has also been in very bad health, have any prospect of assistance from their own immediate relatives, and for this reason I have decided to appeal for him in his sad condition to his professional brethren. Subscriptions will be received and duly acknowledged by his brother, the Rev. Horace Townshend, M.A. Dub. and Camb., Chaplain of Islington Workhouse, 41, King Henry's-road, South Hampstead, and I am authorised by Dr. Buzzard to say that he will start this list with a donation of five guineas, and I shall be happy to give a similar sum myself.

"I am, Sirs, yours faithfully,

"Cavendish-square."

"HENRY MORRIS.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6866 births and 6014 deaths were registered during the week ending Feb. 23rd. The annual rate of mortality in these towns, which had increased in the four preceding weeks from 18.7 to 26.7 per 1000, further rose last week to 29.6. In London the rate was as high as 34.0 per 1000, while it averaged 26.5 in the thirty-two provincial towns. The lowest rates in these towns were 17.4 in Gateshead, 19.8 in Derby, 19.9 in Leicester, 20.3 in Oldham and 20.5 in Hull; the highest rates were 31.5 in Cardiff, 34.0 in London, 35.2 in Nottingham, 38.0 in Plymouth, and 46.1 in Liverpool. The 6014 deaths included 317 which were referred to the principal zymotic diseases, against 312 and 315 in the two preceding weeks; of these, 94 resulted from whooping-cough, 70 from measles, 55 from diphtheria, 43 from diarrhoea, 33 from scarlet fever, 20 from "fever" (principally enteric), and 2 from small-pox. The lowest death-rates from these diseases were recorded in Leicester, Sunderland, Bristol, Swansea, and Birkenhead; and the highest rates in Norwich, Sheffield, Burnley, Manchester, and Salford. The greatest mortality from measles occurred in Bolton, Sheffield, and Gateshead; from scarlet fever in Wolverhampton, Salford, and Huddersfield; and from whooping-cough in Norwich, Manchester, and Burnley. The mortality from "fever" showed no marked excess in any of the large towns. The 55 deaths from diphtheria included 29 in London, 4 in Leeds, 3 in West Ham, and 3 in Sheffield. One fatal case of small-pox was registered in London and 1 in Derby, but not one in any other of the thirty-three large towns. There were 75 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Feb. 23rd, against 51, 56, and 67 at the end of the three preceding weeks; 19 new cases were admitted during the week, against 18 in each of the two preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1658, against 1653, 1667, and

1657 on the three preceding Saturdays; 152 new cases were admitted during the week, against 160, 149, and 159 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 324 to 840 in the four preceding weeks, further rose to 1119 last week, and were as many as 615 above the corrected average. The causes of 107, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Oldham, Leeds, Gateshead, Newcastle-upon-Tyne, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Huddersfield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 23·9 to 35·1 per 1000, further rose to 41·1 during the week ending Feb. 23rd, and exceeded by 11·5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 24·0 in Perth and 24·9 in Aberdeen to 38·0 in Edinburgh and 51·0 in Glasgow. The 1186 deaths in these towns included 51 which were referred to measles, 36 to whooping-cough, 11 to diarrhoea, 7 to diphtheria, 4 to scarlet fever, 4 to "fever," and 2 to small-pox. In all, 118 deaths resulted from these principal zymotic diseases, against 81 and 115 in the two preceding weeks. These 118 deaths were equal to an annual rate of 4·1 per 1000, which was 2·5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 26 and 46 in the two preceding weeks, further rose to 54 last week, of which 22 occurred in Edinburgh, 18 in Glasgow, and 12 in Aberdeen. The deaths referred to whooping-cough, which had increased from 18 to 33 in the four preceding weeks, further rose to 36 last week, and included 30 in Glasgow. The 7 fatal cases of diphtheria differed but slightly from the numbers recorded in recent weeks, and included 4 in Glasgow. The deaths referred to different forms of "fever," which had been 6 in each of the three preceding weeks, declined to 4 last week, of which 3 occurred in Glasgow. The 4 fatal cases of scarlet fever were within 2 of the number in the preceding week, and included 2 in Glasgow. The 2 deaths from small-pox were recorded in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 214 and 345 in the two preceding weeks, further rose to 517 last week, and were more than four times the number in the corresponding week of last year. The causes of 96, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·9 and 34·2 per 1000 in the two preceding weeks, further rose to 35·1 during the week ending Feb. 23rd. During the past eight weeks of the current quarter the death-rate in the city has averaged 33·0 per 1000, against 22·2 in London and 25·5 in Edinburgh. The 235 deaths registered in Dublin during the week under notice showed an increase of 6 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 19 and 17 in the two preceding weeks; of these, 6 resulted from small-pox, 1 from diphtheria, 1 from whooping-cough, 1 from "fever," 1 from diarrhoea, but not one either from measles or scarlet fever. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·5 in London and 5·1 in Edinburgh. The fatal cases of small-pox, which had been 5, 7, and 8 in the three preceding weeks, declined again to 6 last week. During the past eight weeks of the current year as many as 59 deaths from small-pox have been registered within the city. The mortality from "fever" showed a further decline from that recorded in recent weeks. The 235 deaths in Dublin last week included 41 of infants under one year of age and 70 of persons aged upwards of sixty years; the deaths of infants showed a marked increase, while those of elderly persons showed a slight decline from the number recorded in the preceding week. Eight inquest cases and 8 deaths from violence were registered; and 82, or more than a third, of the deaths occurred in public institutions. The causes of 22, or more than 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR ROCHE has been posted to the Western district, and Surgeon-Major Beatty to Belfast. The following officers have embarked in the *Malabar* for India:—Surgeon-Major Dempsey, Surgeon-Captains Sexton and Nicoll, and Surgeon-Lieutenant Farmer. Surgeon-Major Babbie and Surgeon-Captain Burnside have proceeded on a tour of service to Malta.

ARMY MEDICAL STAFF.

Surgeon-Colonel William Christy Robinson retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain D. W. Scotland, Officiating Superintendent, Central Prison, Benares, on being relieved, is appointed to officiate as Civil Surgeon, Jalaun. Surgeon-Lieutenant Bruce Gordon Seton, who has completed three years' full-pay service, is promoted to Surgeon-Captain. Surgeon-Lieutenant-Colonel H. Boyd retires from the service. *Bengal Medical Establishment*: The Queen's approval to the promotion of Surgeon-Lieutenant-Colonel A. B. Seaman to Brigade-Surgeon-Lieutenant-Colonel is announced in the *London Gazette* of Feb. 22nd. The Queen's approval of the retirement from the service of the undermentioned officers is also officially announced:—*Bengal Medical Establishment*: Brigade-Surgeon-Lieutenant-Colonel John Burke Gaffney, Surgeon-Lieutenant-Colonel Andrew McMaster Paterson, Surgeon-Lieutenant-Colonel Horace Parr Yeld.

NAVAL MEDICAL SERVICES.

The following appointments are notified:—Fleet-Surgeons: W. R. White to the *Eagle*; E. W. Luther to the *Durham*. Surgeons: A. O. Bobardt to the *Dart*; H. Meikle to the *Rainbow*.

VOLUNTEER CORPS.

Artillery: 3rd Kent (Royal Arsenal): Luigi Walter Alfred Keiffenheim-Trubridge, M.D., to be Surgeon-Lieutenant. 1st North Riding of Yorkshire (Western Division, Royal Artillery): Henry George Outram Collett, Gent., to be Surgeon-Lieutenant. *Rifle*: The Queen's Rifle Volunteer Brigade, the Royal Scots (Lothian Regiment): The undermentioned gentlemen to be Surgeon-Lieutenants: Alexander Macdonald, M.B.; Claude Buchanan Ker, M.B. 1st Volunteer Battalion, the Royal Warwickshire Regiment: Surgeon-Captain E. L. Freer to be Surgeon-Major.

VOLUNTEER MEDICAL ASSOCIATION.

At the quarterly meeting of this association, held on Jan. 28th, at 20, Hanover-square, it was decided that the next Ambulance Challenge Shield competition should take place on Saturday, June 15th. Squads intending to compete should apply to the Hon. Secretaries, 20, Hanover-square, W., for the conditions regulating the competition, in which some slight alterations have been made. The new regulation by which regimental bearers are no longer allowed to wear the Red Cross badge was discussed, in consequence of numerous representations from members of the association. The conclusion arrived at by the council was that the regulation was necessary in order that the Red Cross may continue to serve as a protection to non-combatants on active service. The wearing of the badge by men in the ranks was really an infringement of the Articles of the Geneva Convention. The annual dinner will take place on April 24th, the date fixed for the annual meeting of the association.

THE ARMY MEDICAL STAFF EXAMINATION.

The following is a list of the successful candidates for commissions in the Medical Staff of Her Majesty's Army at the recent examination in London:—

Names.	Marks.	Names.	Marks.
L. F. Smith	2580	G. T. K. Maurice	2172
S. H. Fairrie	2410	F. E. Gunter	2077
R. J. Blackham	2382	J. H. Campbell	1819
J. V. Forrest	2245	J. Grech	1761
H. W. Graham	2185	P. Dee	1756
R. Fawcett	2175	E. G. E. O'Leary	1611

INDIAN MEDICAL SERVICE EXAMINATION.

The following were successful at the recent examination

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR ROCHES has been posted to the 1st District, and Surgeon-Major Beatty to Baluchistan. Surgeon-Major Dempsey, Surgeon-Captain Seram, and Surgeon-Lieutenant Farmer. Surgeon-Major had Surgeon-Captain Barnside have proceeded on a tour to Malta.

ARMY MEDICAL STAFF.

Surgeon-Colonel William Christy Robinson has retired pay.

INDIA AND THE INDIAN MEDICAL SERVICE.

Surgeon-Captain D. W. Scotland, Officer in Charge, Central Prison, Benares, on being appointed to officiate as Civil Surgeon, Jaipur. Lieutenant Bruce Gordon Seton, who has completed his full-pay service, is promoted to Surgeon-Lieutenant. Colonel H. Boyd returns to service. Bengal Medical Establishment: The approval to the promotion of Surgeon-Lieutenant A. B. Seaman to Brigade-Surgeon, Lieutenant-Colonel announced in the *London Gazette* of Feb. 22. Queen's approval of the retirement from the service of Surgeon-Lieutenant Colonel John Burke Gaffney, Surgeon-Lieutenant Colonel Andrew McMaster Paterson, Surgeon-Lieutenant Colonel Horace Parr Yald.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—*Forster* W. R. White to the *Eagle*; E. W. Luther to the *Surgeons*: A. O. Bobardt to the *Dart*; H. MacRae to the *Rainbow*.

VOLUNTEER CORPS.

Artillery: 3rd Kent (Royal Arsenal): Lieut. Col. Keiffenheim-Turnbridge, M.D., to be Surgeon-Lieutenant, 1st North Riding of Yorkshire (Western Division). Artillery: Henry George Outram (Lieut. Col. Surgeon-Lieutenant. Rifle: The Queen's Buffs (Rifles), the Royal Scots (Lothian Regiment), the mentioned gentlemen to be Surgeon-Lieutenants. Surgeon-Major MacDonald, M.B.; Claude Buchanan Begg, M.B.; Surgeon-Major, the Royal Warwickshire Regiment; Captain E. L. Freer to be Surgeon-Major.

MEDICAL STAFF CORPS IN INDIA.

With regard to the proposed introduction of the Medical Staff Corps into India, put forward in a communication to one of our service contemporaries, we may remark that it is not the first time such a proposal has been made—not that it is any the worse on that account. There is no doubt that it would greatly add to the efficiency in hospital nursing and administration, and at the same time increase the fighting strength of the army in India by not withdrawing soldiers from the ranks (without any hospital training) to act as special orderlies over very sick men. But we are afraid that the military department of the Indian Government are not likely to give practical effect to the suggestion, especially at the present time, on account of the expense. Moreover, the provision of a detachment of the Medical Staff Corps at every military station would require the presence of a considerable strength of that corps in India, with probably a greater liability to sickness and inefficiency than obtains among the native corps and ward servants.

THE FRENCH MINISTER OF WAR AND FRENCH BARRACKS.

The *Army and Navy Gazette* says: General Zurlinden, the French Minister of War, was recently questioned in the French Chamber respecting the outbreak of influenza in Dijon Barracks. He acknowledged that out of 2700 soldiers there had been eighteen deaths, and that 159 men were now in hospital, but he contradicted the rumours of unusual mortality at other places. Here and there he said there were cases of scarlet fever and typhoid fever, but the health of the troops was satisfactory and the army doctors were devoted to their duty. General Zurlinden acknowledged that the allowance of fuel was not sufficient for exceptional winters. He cited a circular issued twelve months ago, in which officers were directed to take precautions to prevent night marches from being detrimental to health.

THE ARMY IN INDIA.

According to the Sanitary Commissioner's Report for 1893 there were only 16 cases of cholera, with 10 deaths, in the whole European army in India in that year; 9 of the cases occurred in Bengal, 6 in Bombay, and 1 in Madras. The year was also about the healthiest on record as far as the native army was concerned; the cholera mortality was only 0.20 per 1000. The chief causes of death were, as usual, in the native army from respiratory diseases.

THE CONTRAST BETWEEN CHOLERA AND NON-CHOLERA YEARS IN INDIA.

There is nothing more remarkable than the contrast which is exhibited in respect of cholera in India between one year and another. The fall that took place in the prevalence of this disease in 1893 was general in almost every Indian province; the mortality from cholera declined from 762,695 in 1892 to 218,113 in 1893. In the case of the Punjab the contrast is very striking. In 1892 the cholera deaths registered amounted to 75,959, whereas in 1893 they only numbered 639.

"Audi alteram partem."

THE TREATMENT OF ACUTE INTUSSUSCEPTION IN INFANTS: EARLY LAPAROTOMY v. INJECTION AND INFLATION.

To the Editors of THE LANCET.

SIRS,—In your last issue you were good enough to publish the report of a case of acute intussusception in an infant upon whom I performed laparotomy with success. In my concluding remarks I urged "that immediate operation should be performed in all cases of twenty-four or more

hours' duration." In your introductory remarks you say: "We are strongly of opinion that these measures [injection of air or fluid] should be tried in all cases where the symptoms have been in existence for less than forty-eight hours, and that laparotomy should be recommended if injection has failed." As these views are somewhat opposed to each other I should be glad if you would permit me to state the reasons for the practice I advocate. I have carefully studied the published reports of twenty-six fatal laparotomies for acute intussusception in children of two years or younger. From these accounts it appears that the average duration of the symptoms before operation was three days and a half. In only five cases was the duration of symptoms two days or less. It is instructive to notice the causes of death in these cases. They are as follows:—

Cause of Death in Five Fatal Cases of Laparotomy.

No.	Date.	Surgeon.	Age and sex.	Duration of symptoms.	Cause of death.
1.	1877	Beck	F. 8 months	26½ hours	Acute peritonitis. ¹
2.	1882	Marsh	" "	2 days	Death two days after operation; temperature 106° F. ²
3.	—	Jacobson	F. 11 months	24 hours	Irreducible; operation abandoned. ³
4.	1885	Horsley	M. 5 months	19 hours	No shock; died cyanosed; lungs congested. ⁴
5.	1894	Barker	" "	2 days	Local peritonitis; temperature 107° F. ⁵

¹ Brit. Med. Jour., vol. i. 1894, p. 346. ² St. Bartholomew's Hospital Reports, vol. xxviii. ³ THE LANCET, June 11th, 1887, p. 1179. ⁴ Brit. Med. Jour., vol. i. 1894, p. 346. ⁵ Brit. Med. Jour., vol. ii. 1894, p. 1237.

I have also found records of sixteen successful operations for the same condition.

Successful Laparotomies for Acute Intussusception in Infants.

No.	Date.	Surgeon.	Age and sex.	Duration of symptoms.
1.	1875	Marsh	7 months	13 days (acute 12 hours) ¹
2.	1877	Sands	6 "	1 day ²
3.	1881	Godlee	9 "	4 days ³
4.	1888	Snowball	8½ "	24 hours ⁴
5.	1889	Barker	F. 5 "	2 days ⁵

16.	1893	Roughton	F. 4 "	24 "

¹ THE LANCET, June 11th, 1887, p. 1178. ² THE LANCET, June 11th, 1887, p. 1178. ³ THE LANCET, Nov. 3rd, 1888, p. 888. ⁴ Brit. Med. Jour., Feb. 17th, 1894. ⁵ St. Bart's Hosp. Rep., vol. xxviii. ⁶ St. Bart's Hosp. Reports, vol. xxviii. ⁷ Med. Record, 1890, p. 114. ⁸ THE LANCET, Oct. 15th, 1892, p. 880. ⁹ St. Bart's Hosp. Reports, vol. xxviii. ¹⁰ Brit. Med. Jour., Feb. 17th, 1894. ¹¹ THE LANCET, June 3rd, 1893, p. 1303. ¹² Brit. Med. Jour., Feb. 17th, 1894. ¹³ THE LANCET, Feb. 24th, 1894. ¹⁴ Brit. Med. Jour., Dec. 1st, 1894. ¹⁵ Brit. Med. Jour., Dec. 23rd, 1893. ¹⁶ THE LANCET, Feb. 23rd, 1895.

From this table it appears that the average duration of the symptoms in the successful cases was only thirty-two hours, in no less than 10 of the 16 cases it was twenty-four hours or less, and in only 3 cases was it two days or more. These facts, I think, fully justify my contention, and prove, as far as they can, that if laparotomy is to be attempted with any reasonable chance of success it must not be deferred longer than twenty-four hours from the onset of the disease. I cannot help thinking that the amount of shock caused by abdominal section in these cases has been confounded with that produced by the disease itself, and by the previous unsuccessful attempts at reduction by inflation and injection. I do not

think that the shock of a skilfully and rapidly performed laparotomy is greater than that produced by injection when sufficient force is used to disengage the invagination. The dangers and uncertainty of inflation and injection have been well shown by Lawford Knaggs¹ and Mortimer.² I am convinced that a wider appreciation of the dangers of injection and the success of early laparotomy will do much to reduce the mortality of the disease; and this, Sirs, I must ask you to accept as my excuse for having had the temerity to question the views you have expressed.

I am, Sirs, yours faithfully,

Westbourne-terrace, W., Feb. 25th, 1895. E. W. ROUGHTON.

* * We print Mr. Roughton's interesting letter with pleasure, but we still consider that our recommendation of a trial of the injection of air or fluid in these cases previously to abdominal section, where the symptoms have been in existence less than forty-eight hours, a sound one. In careful hands these measures are comparatively unattended with risk, and are likely to be successful in a majority of cases treated within the specified time. We do not recommend that operation should be deferred after an unsuccessful attempt has been made at reduction by other means, no matter how recent the symptoms may be.—ED. L.

THE FEVERS OF INDIA AND THE MEDITERRANEAN.

To the Editors of THE LANCET.

SIRS.—I have read with much interest in THE LANCET of Jan. 19th last the Presidential Address in Medicine and Pathology at the Indian Medical Congress by Surgeon-Lieutenant-Colonel Crombie, I.M.S. In attempting to classify the "fevers of India" into specific groups and varieties he has grappled with a question which for years has been a stumbling block in our official nomenclature of diseases, not only in India but in the Mediterranean and elsewhere. In this nomenclature we find: 1. Malarial fevers, subdivided into (a) intermittent fever; (b) remittent fever; and (c) malarial cachexia; a subdivision founded in the two former cases on a single clinical characteristic not confined to any individual specific fever. 2. Enteric fever well known and carefully defined, but having a subheading termed "typho-malarial fever," a combination of malarial and enteric fever. 3. Simple continued fever defined as "continuous fever, having no obvious distinguishing character." Paludism, which has now been fairly proved to be the result of Laveran's hæmatophyllum, is the condition at present commonly accepted as true malarial fever. According to the variety, quantity, or quality of the virus in given cases, so it is believed the pyrexial curve becomes intermittent, remittent, or continuously high, but the disease is of a paroxysmal nature and amenable to quinine. Malarial cachexia is accepted as the result of the prolonged action on the body tissues of the same parasite. Enteric fever, though a well-defined specific fever, frequently runs a most remittent course, while cases of tuberculous suppuration may be most intermittent in type, yet no one would dream of diagnosing either of these pyrexial conditions as "malarial fevers." The greater part, however, of the remaining fevers of tropical and subtropical regions which have not yet been definitely named must, if of a remittent or intermittent character, be classified either with paludism, as malarial fevers, or as simple continued fevers, however many obvious distinguishing characters they may possess. Surgeon-Lieutenant-Colonel Crombie deals with four such types of non-malarial fevers occurring in India, two of which he ventures to think are specific forms. Three types are especially interesting to medical officers serving in Malta, as very analogous forms of fever exist and are endemic in that and other places in the Mediterranean, which for want of better names are in the army with sad irony diagnosed as "simple continued fever" in spite of most obvious distinguishing characters and a difference in duration of any time between two and 200 days' stay in hospital. Paludism these cases certainly are not, as this form of fever is not endemic in Malta, and occurs only in the form of relapses in men who have previously suffered from the disease in Cyprus, India, Mauritius, or elsewhere. They may, however, be intermittent, remittent, or continuously high in

pyrexial type, but are non-paroxysmal in nature and unamenable to quinine.

1. The first of these is "simple ardent fever" or febricula, a short fever of from three to six days' duration met with in almost every country, and doubtless specific. 2. Next there is an acute fever of about fourteen days' duration, similar to the form termed "Calcutta or Bombay fever" by Surgeon-Lieutenant-Colonel Crombie. Though diagnosed simple continued fever, it is usually said to be abortive enteric, and in pyrexial curve it resembles a case of enteric fever telescoped into a fortnight. It is, however, devoid of any other clinical resemblance and has every appearance of being a distinct fever. To my knowledge it occurs in Malta, Gibraltar, and Egypt. 3. Thirdly, there is a low form of fever varying between 99° and 101.5° F. (when taken morning and evening), never being normal, and occasionally remaining for from four to six weeks continuously between 99° and 100°. This is generally associated only with anorexia, anæmia, and debility, but may also be combined with neuralgic or rheumatic symptoms. It is not common, and is generally merged into the next class of fevers. Whether it is similar to the "low fever" of Surgeon-Lieutenant-Colonel Crombie and a specific disease I cannot say. 4. Lastly, there is the fever known as Malta, Rock, and Mediterranean fever, pseudo-typhoid, fæco-malaria, &c. It has an irregular course, an indefinite duration, may vary in pyrexial type, but is characterised more especially by its length, tendency to relapse, constipation, anæmia, and rheumatic and neuralgic complications. In severe cases the temperature becomes continuously high, and, combined as they then are with a tendency to the "typhoid state," lead to a similarity in clinical characters to enteric fever. Other cases may in pyrexial curve almost seem to be enteric fever, followed by five or six relapses. The majority, however, are clearly and definitely distinct, and in the few fatal cases (under 2 per cent.) not only are Peyer's patches unaffected, but a characteristic micrococcus, capable of producing a similar fever in monkeys, replaces Eberth's bacillus. Certain cases, again, become intermittent in type, but non-paroxysmal, and resemble the hectic pyrexia of phthisis. Cases of this fever, though diagnosed as simple continued fever in the army, are by the naval and civilian medical men diagnosed as "remittent fever," and together with remittent paludism, and under the heading of malarial fevers.

The time appears to have come when malarial fevers and malarial cachexia should be classified as one group, under such a name as paludism, and be recognised as the results on the body tissues of Laveran's amœbe, any necessary subdivisions being based on more scientific data than one clinical feature common to many fevers. Let "typho-malarial fever" be also abolished, and such conditions be diagnosed according to the disease at the time the more serious, as would be done in the event of enteric fever occurring in a patient already suffering from constitutional syphilis. This will leave a number of fevers at present termed "continued" without definite names, but these forms will, on account of their obvious distinguishing characters, soon find names when the vague terms "intermittent" and "remittent" fever are abolished. More accurate clinical observation and epidemiological and biological research must soon settle the question, as has been done in the cases of typhus, enteric, and paludic fevers, for every year the circle is closing in. In conclusion, let us hope, with Surgeon-Lieutenant-Colonel Crombie, that England will not yield the palm of discovery to Germany or France in this matter.—I am, Sirs, yours faithfully,

M. LOUIS HUGHES.
Surgeon-Captain, A.M.S.

Malta Jan. 28th, 1895.

THE TREATMENT OF INFLUENZA.

To the Editors of THE LANCET.

SIRS.—As we are in the midst of another widely spread epidemic of influenza I should like to call attention to the routine and somewhat reckless use of such drugs as salicin and antipyrin, which I observe is still common in the treatment of this malady. After between four and five years' experience and observations of the effects of various methods of treating influenza I have been unable to resist the conviction that these drugs, while they doubtless relieve some of the most distressing early symptoms, possess no real

¹ THE LANCET, Dec. 12th, 1892, and Annales de l'Institut Pasteur, August, 1893.

erial type, but are non-paroxysmal in nature, and amenable to quinine.

The first of these is "simple ardent fever" which is short fever of from three to six days' duration, and is met with in every country, and doubtless specific. It has an acute fever of about fourteen days' duration, and is termed "Calcutta or Bombay fever" by Surgeon-Lieutenant-Colonel Crombie. Though diagnosed as ardent fever, it is usually said to be abortive, and its pyrexial curve it resembles a case of enteric fever, and lasts for a fortnight. It is, however, devoid of any enteric resemblance and has every appearance of being a simple fever. To my knowledge it occurs in India, China, and Egypt. 3 Thirdly, there is a low fever varying between 99° and 101.5° F. (when taken in the morning and evening), never being normal, and continuing for from four to six weeks, commencing between 99° and 100°. This is generally associated with anorexia, anemia, and debility, but may be combined with neuralgic or rheumatic symptoms. It is common, and is generally merged into the next fever. Whether it is similar to the "low fever" of the Lieut. Colonel Crombie and a specific disease, Surgeon-Lieutenant-Colonel Crombie and a specific disease, it has an irregular course, an indefinite duration, and is pyrexial type, but is characterised more especially in length, tendency to relapse, constipation, and rheumatic and neuralgic complications. In several cases the temperature becomes continuously high, and then they then are with a tendency to the "typical" curve, to a similarity in clinical characters to enteric fever. Cases may in pyrexial curve almost seem to be entered, followed by five or six relapses. The majority, however, clearly and definitely distinct, and in the few cases (under 2 per cent.) not only are Peyer's patches absent, but a characteristic micrococci, capable of passing a similar fever in monkeys, replaces Eberth's bacilli. In cases, again, become intermittent in type, and paroxysmal, and resemble the hectic pyrexia of phthisis. Cases of this fever, though diagnosed as simple, are by the naval and civil medical officers in the army, are by the naval and civil medical officers, and under the heading of malarial fever, paludism, and have come when malarial fever. The time appears to have come when malarial fever should be classified as one of the malarial fevers, and be recognised as such, such a name as paludism, and be recognised as such, the body tissues of Laveran's amoebae, any malarial divisions being based on more scientific data, clinical feature common to many fevers. "Malarial fever" be also abolished, and malarial fever diagnosed according to the disease at the time of diagnosis, as would be done in the event of malarial fever occurring in a patient already suffering from syphilis. This will leave a number of fevers termed "continued" without definite names. Forms will, on account of their obvious characters, soon find names when the names "remittent" and "intermittent" fever are abolished. I rate clinical observation and epidemiological research must soon settle the question, as the year the circle is closing in. In conclusion, I am with Surgeon-Lieutenant-Colonel Crombie, the fever not yield the palm of discovery to Germany or France.

Malta Jan. 25th, 1895.

THE TREATMENT OF INFLUENZA

To the Editors of THE LANCET.

SIRS,—As we are in the midst of another mild epidemic of influenza I should like to call attention to a routine and somewhat reckless use of such drugs as antipyrin, which I observe is still common in the treatment of this malady. After between four and five years' experience and observations of the effects of various treatments of influenza I have been unable to perceive any advantage in the use of these drugs, while they do cause some of the most distressing early symptoms, such as

antitoxic influence over this affection, and not only leave the patient exposed to all the serious after-effects of the influenzal intoxication, but even render him more susceptible to some of them. The drugs, which I notice are now often prescribed in combination, are all the more dangerous, because their immediate effects are usually pleasant both to the patient and the practitioner. The patient is pleased to have the more painful symptoms speedily relieved and the practitioner is pleased to have the credit of being able to relieve them. But patients who have been thus treated often have a tedious convalescence, and are very subject to recurrent attacks of cardiac debility as well as to other serious sequelae. I have often been struck with the pale, exhausted, worn, and shrunken aspect of some of these "convalescents." On the other hand, both clinical and experimental evidence point to quinine as a true antitoxin in influenza. No doubt many persons complain much of certain disagreeable effects which full doses of quinine occasionally produce; but these should, in most cases, be looked upon as a small evil compared with the grave after-effects which are especially apt to occur when quinine has not been adequately or suitably administered. In malarious countries no medical practitioner would feel justified in withholding quinine because of any supposed "intolerance" of that remedy. I have elsewhere pointed out how much better quinine is tolerated by many persons, and how much more beneficial its action appears to be when given in combination with an alkaline saline; but my object now is to point out that the use of such drugs as salicin and antipyrin should be restricted to two or three doses given simply for the relief of the pains attending the onset of the disease; that they are harmful if given freely and as a matter of routine; and that we should rely mainly upon quinine as a proved antitoxic agent in this disease. The present widely diffused outbreak on the cessation of the protracted frost seems to point to the sudden mobilisation of the imprisoned bacilli, or possibly to the suspension of their infective activity during the prevalence of the very low temperature.

I am, Sirs, your obedient servant,
I. BURNETT YEO, M.D., F.R.C.P.,

Professor of Clinical Therapeutics in King's College.
Hertford-street, Mayfair, Feb. 25th, 1895.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."

To the Editors of THE LANCET.

SIRS,—The only comment necessary upon Sir George Johnson's last letter is to remark that the words following Dr. Halliburton's statement about there being enough to convince the impartial observer that a small quantity of glucose is obtainable from normal urine did not stand in the position of being held back by me, inasmuch as the text in full had been the previous week before your readers. Passing to Dr. Halliburton's letter, I am asked to amplify my position with respect to the detection of alcohol by the chromic acid test. This matter was incidentally introduced in a quotation from the Guy's Hospital Reports for 1876 detailing the application of the fermentation test at a meeting of the Royal Medical and Chirurgical Society in 1875. It is perfectly true, as stated by Dr. Halliburton, that a number of volatile organic principles react with chromic acid in the same manner as alcohol; but I doubt not that Dr. Halliburton will admit that to get the reaction one or other of these principles must be present, and that for their presence there must be a source for them. Now, the product submitted to the action of the fermentation test consisted of an aqueous solution of the extracted sugar obtained by liberation from its lead compound, and the solution had been previous to employment concentrated by evaporation in an open capsule. Hence, if it had been possible—and I contend it was not—for one or other of these principles to be present it would have been dissipated in the process of evaporation, leaving the alcohol generated by fermentation as the only agent permissible to look to for the reaction that was observed. Dr. Halliburton's invitation to enter upon a discussion of the question of kreatinine I am not tempted to accept.

I am, Sirs, yours faithfully,
Grosvenor-street, Feb. 27th, 1895. F. W. PAVY.

* * This correspondence must now cease. If none of the parties to it have exactly convinced each other, they have made sufficiently clear the points at issue between them, and

it is possible that the debate between authorities so well qualified to hold strong opinions on the subject will stimulate others to assist the profession at arriving at a definite conclusion on a very interesting point.—ED. L.

"THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—Dr. Lovell Drage has hitherto written so ably on the question of midwives' registration that I was disappointed on reading his letter to find only a *réchauffé* of the old stock arguments. However, the very pertinacity of their appearance demands a categorical answer. We are apparently now all agreed that something must be done, but to be effectual what is done must be done with the consent of the great majority of the profession, and must have its cordial support. Again, we are mostly agreed that proper education and efficient control are the points aimed at. The Obstetrical Society have endeavoured to fulfil the first condition, but are absolutely helpless as regards the second, and it is with a view to obtaining this power of control that registration is asked for. I admit that the present method of granting diplomas by the Obstetrical Society has great drawbacks, but accept it on the principle that half a loaf is better than none. It would be surprising if no fault or omission could be found in the regulations for an examination, but in the instance quoted the society have evidently very properly shown their appreciation of the defect by the issue of the circular mentioned. Dr. Drage complains that certain representations on the subject have been unheeded. I thought they were old and well-known friends. The first statement as to mortality statistics is weakened by the want of a full knowledge of all the factors, without which any figures become little more than decorations for a discussion. We want to know the rates before there was State control. We want the rates both in those cases attended by registered midwives and in those attended by uneducated midwives. We at least should know the proportion of cases attended by the State-controlled midwives, especially as we are told in the next paragraph that the system has not resulted in removing the unqualified practitioner. It must be remembered that it is not only or chiefly mortality-rate, but sickness-rate, both direct and indirect, that we have to consider. Registration, I admit, will not immediately or absolutely remove the unregistered practitioner. We are reluctant to interfere with vested interests, so the continuance and maintenance of untrained midwives constitute one of those difficulties that are inseparable from the establishment of a new system. How long it will last and how much it will flourish will depend on the support which any new system receives from the profession whose duty it will be to educate the people to an appreciation of their danger and the ways of safety; therefore am I most anxious that some means may be found of settling this vexed question. That midwives do not send for the surgeon for the repair of the perineum must be a fault of education and training, but one that may apply to not a few qualified medical men in large practice; but, even admitting this fault, the midwives at any rate know the danger, and are in a better position to rectify it than a nurse without any education. Secondly, it is objected that of the 2000 diplomates of the Obstetrical Society few are found practising among the poor except as the employees of institutions or charities. This is surely the best thing that could be wished for; here we have the desired condition of control, and very efficient it is, and what, may I ask, could these charities have done without the much-reviled society to select efficient midwives for them to employ? It is doubtful whether a trained midwife in a country district would be able to earn a sufficient competence to make it worth her while to go through a comparatively expensive training. And I believe that a solution will be found in the village nursing associations that are now coming into existence in so many places, and which guarantee the expenses of a nurse who is both district nurse and midwife, and I trust that the time may come when the guardians of the poor may see fit to act in the same capacity as the nursing associations. But we shall never get out of the difficulty if we wait for the perfection that is shadowed in Dr. Drage's third statement, that midwives shall not be certified because "certified midwives have been found guilty of criminal practices"; surely not our own or any other profession or any class of society in this.

world can claim the required maiden record of virtue and blamelessness. Whatever may be done, I trust the little help we have in the finding of efficient midwives for the poor may not be taken from us until something better is provided.

I am, Sirs, your obedient servant,
Freshford, Feb. 25th, 1895. CHAS. E. S. FLEMMING.

To the Editors of THE LANCET.

SIRS,—Dr. Playfair, in his letter in THE LANCET of to-day, has appended the form of "diploma" issued to midwives by the Obstetrical Society of London, but he has not informed us how the women obtain their knowledge of the art to be considered by the society skilled midwives "competent to attend natural labour." At our lying-in hospitals in London, and at the celebrated Rotunda in Dublin, their certificated midwives are required to undergo practical training &c. in the wards before they are considered eligible to offer themselves for examination, which necessarily goes very far to render them "competent." But if the respective candidates for the Obstetrical Society's "diploma" are relieved from this highly essential mode of acquiring experience in this most important branch of the medical profession, but are simply admitted to examination after "cramming" from one of the smaller manuals upon the subject, that is quite another matter, which, I maintain, would be insufficient to make them competent "to deal with a natural labour," for even this natural process would assuredly mislead them sooner or later. Wherefore is there any need for the "diploma" of the Obstetrical Society of London at all—excepting from a purely financial point of view—when the above recognised excellent institutions grant them after a searching ordeal? We may yet look forward to the Medical Society of London awarding to candidates a diploma in medicine and the Royal Medical and Chirurgical Society a diploma in surgery! Undoubtedly these societies have quite as much power to do so.—I am, Sirs, yours faithfully,
Putney, S.W., Feb. 23rd, 1895. J. FRENCH BLAKE.

To the Editors of THE LANCET.

SIRS,—Dr. Playfair is apparently content with the policy of evasion so characteristic of the friends and allies of the Midwives' Institute. He will perhaps pardon me for stating that it is not a question of my views, it is a question of facts. As he cannot upset the facts put forward, he talks of dialectic devices. The plain truth of the matter is, the Midwives' Institute and its confederates, not being able either to show in any way that the Continental system of midwifery practice is anything but a bad one, or to support their views in public successfully, are attempting to introduce this system by subterfuge. The action of the General Medical Council, if justified by nothing else, is so by the slipshod method of examination carried out by the Obstetrical Society. The council of that society intend by their diploma to show that the holder is fit to practise ordinary midwifery. That it is used as a diploma for practice was demonstrated to that council. If the intention of the majority on that council is not to induce their licensees to practise ordinary midwifery, why will it not agree to make it quite plain that the certificate or diploma does not entitle the holder to practise midwifery? Their policy is one of evasion; they intend to issue such a certificate with definite intention; they procrastinate so as to bring a little lobbying influence to bear on the members of the General Medical Council. Wrapt up in true College of Physicians dignity, Dr. Playfair is quite content to tell the House of Commons that he has not paid the same attention to the subject as he did twelve years ago, but that his impressions are those of the profession; that his opinion is that because midwives are recognised by the State in some countries therefore they should be so in this country. In fact, like the College of Physicians practitioner of 150 years ago, he conceals ignorance by an outward appearance of great wisdom.

I am, Sirs, yours faithfully,
Feb. 25th, 1895. LOVELL DRAGE.

"LIFE ASSURANCE SCHEMES."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 16th, in an annotation entitled "Life Assurance Schemes," a comparison is instituted between the Royal Exchange Company's new policy and the debenture policy of the Mutual Life Insurance Company of New York. I venture to suggest that the writer has not

made himself acquainted with the nature of that policy as issued by this company. He asserts that under our policy "part benefit only is enjoyed" during the first twenty years, whereas, as a matter of fact, if the death occurs after payment of the first premium the whole of the benefits vest at once. It is also his mistake to suppose that "one-half only of the sum assured becomes payable" at death, "the payment of the other half being deferred for twenty years upon payment in the interval by the company of interest on the withheld balance at the rate of 5 per cent." The policy is much more simple. It provides that whenever death occurs the beneficiary becomes entitled to 5 per cent. upon the full amount insured for twenty years, and the capital amount assured at the end of twenty years. The assured may, in addition, contract for a guaranteed progressive bonus during the first twenty years, but this is an option not confined to our debenture policy. It is not my suggestion that this is a policy in anywise comparable with that issued by the Royal Exchange. We seek to give an increasing insurance for a fixed annual payment—that office offers what appears to be decreasing insurance. I may, however, be allowed to point out that when the writer says the object of the English company is "to give as large an immediate return as possible upon the premiums charged, and for this purpose the distant future is sacrificed to the near," it is only by the immediate death of the assured that an immediate return can be had, the argument being that the assured must die to gain. We seek to make his assurance valuable, whether he lives or dies. The writer says: "It is a grievous mistake to be led away by the prospect of personal advantage in the distant future from making the largest possible provision for the contingencies of the near future." Now, the function of the medical officer in life insurance is to make the "contingencies of the near future" available only to the few, while the distant future is certain. The advice given would mean that a man should make up his mind to die in the near future, and fix a term within which it should occur, and then insure for that term—e.g., a man aged thirty, believing he will die within five years, if he can get assured would have to pay us only £13 15s. 10d. for £1000. If he died before his second premium fell due his estate would gain £986 4s. 2d. Under the Royal Exchange policy he would be charged £15 5s., and his estate would gain only £978 1s. Thus the Royal Exchange method is not the cheapest for a man who is prepared to back his early death. But this is not pure life insurance. It is a gamble.

If it be true, as stated, that the Royal Exchange method "may probably have the effect of cancelling the insurance in the case of persons who live to extreme old age," I can only say that my company would not compete for such a result. Our policies are "very distinct in character," as you truly state.

I am, Sirs, yours truly,
D. C. HALDEMAN,
General Manager of the Mutual Life Insurance
Company of New York.

Cornhill, London, Feb. 25th, 1895.

* * It is odd that our correspondent should complain. We said that one-half of the sum assured remained on credit with the company for twenty years after the death of the life assured. He says that the whole amount is so withheld. Be it so. The correction is material, but does not make the scheme of assurance in question any more attractive, for a round sum of money in hand is often in the circumstances contemplated a priceless boon to widow and orphans, against which a 5 per cent. investment simply does not count. The very old gibe that a temporary life assurance is "a gamble" ought really to be superannuated now. It has been so often refuted and is so obviously devoid of point as to be no longer fit for work. Of course, Mr. Haldeman's company may refuse to compete for such business—that is a question for his directors,—but he assumes too much when he assumes to scold at the customers of other companies who, knowing what they want in the way of life assurance, elect to go where they can get it.—ED. L.

COLOUR VISION AND ACCIDENTS.

To the Editors of THE LANCET.

SIRS,—For many years keen attention has been paid to this question and examinations instituted. Has any accident

Volume 13

while himself acquainted with the nature of the business transacted by this company. He asserts that while no part benefit only is enjoyed "during the first twenty years," whereas, as a matter of fact, if the death occurs before the end of the first premium the whole of the sum assured is paid. It is also his mistake to suppose that "one-half of the sum assured becomes payable" at the expiration of the first year; the other half being deferred till the second year. Payment in the interval by the company does not mean that the withheld balance at the rate of 5 per cent. "is much more simple." It provides that where it occurs the beneficiary becomes entitled to receive the full amount insured for twenty years after the amount assured at the end of twenty years has been received may, in addition, contract for a small progressive bonus during the first twenty years. This is an option not confined to our defective policy, but I do not miss the suggestion that this is a policy in agreement with that issued by the Royal Exchange Assurance Office offering insurance for a fixed annual premium which appears to be decreasing every five years, however, be allowed to point out that what we say the object of the English company is to give an immediate return as possible upon the premiums paid for this purpose the distant death of the insured near," it is only by the immediate death of the insured that an immediate return can be had. But in making that the assured must die to gain, he makes his assurance valuable, whether he lives or dies. The writer says: "It is a grievous mistake to be guilty of prospect of personal advantage in the case of making the largest possible provision for the near future of the near future." Now, the fraction of the life insurance is to make the "contingent future" available only to the few who die in the near future is certain. The advice given would be to should make up his mind to die in the near future term within which it should occur, and the best term—e.g., a man aged thirty, believing he will live five years, if he can get assured would have to pay £13 15s. 10d. for £1000. If he died before the end of five years full due his estate would gain £868 10s. 10d. The Royal Exchange policy he would be charged £13 15s. 10d. for £1000. If he died before the end of five years his estate would gain only £973 10s. 10d. Thus his estate would gain is not the cheapest method of securing back his early death. But this is a gamble.

If it be true, as stated, that the British Insurance Company probably have the effect of excluding persons in the case of persons who live to extreme old age, only say that my company would not care to result. Our policies are very distinct in character. I am, Sirs, yours truly,
D. C. HANCOCK
Secretary to the National Life Insurance Co., Ltd.

Queen Anne-street, W., Feb. 26th, 1895. W. R. GOWERS.

To the Editors of THE LANCET.

Sirs,—Under the above heading at p. 361 of THE LANCET of Feb. 9th you refer to the occurrence in 1893 of two cases of small-pox amongst the patients in the scarlet fever pavilion of the Stockport Isolation Hospital, the first of which was primarily attributed to the fact that a cat secretly kept in the scarlet fever pavilion had visited the small-pox pavilion, though both cases were ultimately believed to be the result of direct communication between these pavilions by means of a tunnel or subway, 77 ft. in length, for the heating pipes, the existence of which was subsequently discovered. In questioning the soundness of this conclusion you object that: 1. "Nothing is said as to the condition of the patients as to vaccination." Your point is not quite clear to me, but the facts are as follows:—Case 1: Aged two years and a half; admitted Jan. 13th; papular rash Feb. 15th. Two rather faint vaccination marks on the left arm, each slightly smaller than a threepenny piece. Small-pox well marked and ended fatally on Feb. 18th. This child had a tuberculous knee-joint with sinuses. Case 2: Aged seven years; admitted Jan. 23rd; papular rash Feb. 28th; three good vaccination marks on left arm almost exactly the size of a sixpenny, a shilling, and a halfpenny piece respectively. This patient on admission was suffering from diphtheria, and was isolated in a separate small ward of the scarlet fever block. This small ward freely communicated with the scarlet fever ward proper, and this child when convalescing from diphtheria developed scarlet fever, and was then put in the scarlet fever ward in which Case 1 and several other children were under treatment. Upon the occurrence of Case 1 all children over seven years of age in the scarlet fever pavilion were at once revaccinated, with the single exception of Case 2, whose marks were so large and good that her revaccination was not considered necessary. 2. You suggest that Case 2 may have derived its infection from Case 1. This is of course possible, and even probable judging from the dates, but it does not, I submit, in any way weaken my contention as to the mode of primary introduction of infection to the pavilion. 3. You say: "And, again, may not both cases have derived their infection aerially?" Certainly, I have not the least doubt that they did so—Case 1 directly from the small-pox pavilion through the underground passage, and Case 2 either in the same way or from the air of the ward infected by Case 1. The odour of oil of peppermint poured with boiling water into the aperture of exit of the heating pipes in the small-pox pavilion quickly pervaded the whole of the scarlet fever pavilion, and this, together with the significant fact that no further case of secondary small-pox occurred after two brick partitions faced with cement concrete had been built across the tunnel of communication, leaves no doubt whatever in my mind as to the part played by the tunnel in question.—I am, Sirs, yours faithfully,

Stockport, Feb. 20th, 1895.

CHARLES PORTER.

To the Editors of THE LANCET.

SIRS,—Allow me briefly to reply to the kindly comments on my paper with the above heading made by two skilled anaesthetists. I have repeatedly heard it alleged that in giving a mixture of ether and chloroform in an inhaler you are working with a vapour composed of the same proportions of its constituents as exist in the liquid form. It was to show the fallacy of this belief that I made the researches detailed in my paper. I there proved that in working with such a mixture you were giving an inhalation varying continually in the relative percentages of its constituents, and I

expressed my belief that to use such a mixture was unscientific and unsafe. When dealing with lethal weapons let us know at least what we are using. I should not like your readers to infer that this mixture is, as one of your correspondents suggests, my mixture at all. I have seen it much used here and I have heard of it being largely used elsewhere, but, of course, the A.C.E. mixture is the much more commonly used one. I had this mixture in my mind's eye, but expressly avoided examining residues from such for the following reasons.

1. If variations in the strength of inhalations were shown to result from mixing two liquids, *a fortiori* would you get such variations from mixing more than two together? Let us always begin by the simpler hypothesis.
2. As algebraists well know, to calculate values of X and Y is an easy matter; to calculate values of X, Y, and Z is far more arduous. The relative amount of ether and chloroform can be easily calculated from the specific gravity. In the case of three liquids soluble in each other it is possible, perhaps, to calculate the percentage of each from the volume and density, but it is a task beyond my powers. The three might be separated by fractional distillation; or an estimation might be made by distilling off the ether by a gentle heat and oxidising in half the residue the alcohol into acetic acid and titrating with alkali, whilst in the other half the chloroform would be converted by boiling with caustic potash into chloride and formate of potassium. These methods would take a considerable time—much more than I could well spare.

As to what would most likely take place with the A.C.E. mixture in a Clover's Inhaler, the relative rate of the three constituents are : alcohol 100, ether 78.7, and chloroform 62. Ether boils at 35°C. (95°F.), and will generally be gently boiling in a Clover if the room is warm—warm as operating rooms usually are. The boiling points of chloroform, 62.7°C. (145°F.), and alcohol, 78.5°C. (173°F.), are too high to enter into the question. The low boiling point of the ether would probably compensate for its less diffusion power as compared with alcohol, and the two vapours might to some extent correspond in amount to each other. The chloroform, handicapped by its low diffusion rate and having no low boiling point to help it onwards and upwards, would linger longer, becoming stronger and yet stronger, until at last, like Astræa, "ultima terras relinquat." My conclusion is that when mixtures are administered homogeneity of inhalation is only possible when the anæsthetic is added by drops on to the face of an open mask; that, in fact, mixtures should not be given in a closed inhaler.

I am, Sirs, yours faithfully,

Derby-road, Nottingham, Feb. 23rd, 1895. EDGAR B. TRUMAN.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow us to inform your readers that the subscription list of the above will be closed next month, and that it has been decided to spend part of the money in the erection of a memorial tablet in Guy's Hospital Medical School and to hand the balance to Dr. Rake's widow and children. It may have been supposed that the latter were sufficiently provided for under the will of the elder Dr. Rake; we therefore wish to say that the small extent to which they become beneficiaries was known to us, and that the whole question was considered at two meetings of the committee before the appeal was drawn up which you kindly inserted in your columns. The treasurer of the fund, Dr. Pye-Smith (48, Brook-street, W.), will still be glad to receive contributions from other friends who appreciated the character and work of the late Dr. Beaven Rake, but who have not yet subscribed to the memorial.

We are, Sirs, yours faithfully,

PHIN. S. ABRAHAM

GEORGE A. BUCKMASTER } Hon. Secs.

ALFRED RAKE.

To the Editors of THE LANCET.

SIRS.—Not having been re-elected to the post of anaesthetist to the Chelsea Hospital for Women, I feel I should like, with your permission, in justice to myself to state the circumstances of the case. When the staff resigned in consequence of the report of the Committee of Inquiry, as no questions of the anaesthetic work of the hospital had been raised it did not seem necessary for me to resign my post. In December,

General Insurance Company.
Cornhill, London, Feb. 25th, 1880.

* * It is odd that our correspondent should say
said that one-half of the sum assured remained
with the company for twenty years after the de-
life assured. He says that the whole amount is
De it so. The correction is material, but does not
scheme of assurance in question any more than
round sum of money in hand is often in the con-
contemplated a priceless boon to widow and orph-
which a 5 per cent. investment simply does not
very old gibe that a temporary life assurance is
ought really to be superannuated now. It is
refuted and is so obviously devoid of point as to
fit for work. Of course, Mr. Hutton's
refuse to compete for such business—that is
his directors,—but he assumes too much when he
scoffed at the customers of other companies
what they want in the way of life assurance
where they can get it.—E. L.

COLOUR VISION AND MORE
To the Editors of THE LANCET
has been attended to

however, the treasurer represented to me as everyone had resigned it was desirable that I should do so, and I fell in with his suggestion. In due course the applications for the in- and out-patient staff were advertised for, but the post of anaesthetist was not advertised for till Feb. 2nd. My application therefore did not come before the Medical Selection Committee in the early part of January. Although the board advertised that candidates must not be engaged in general practice I applied for re-election, stating I had served the hospital as anaesthetist for three and a half years and that I had had no fatal case. There has never been any fault found with my work. I claim to take all necessary care as regards antiseptic precautions, and I fail to see that my work as a practitioner should disqualify me for a post which I have held with success for so long. I am, Sirs, yours faithfully,

ANDREW FAUSSET, B.A., M.B., B.Ch. Dub.

"THE DANGERS OF STREET PENNY TOYS: A PROTEST."

To the Editors of THE LANCET.

SIRS,—With reference to your annotation concerning the danger of cheap toys and the possibility of diffusion of disease by the mouth, allow me to remind you of an instance of the kind reported in the French press somewhere about 1877. A number of persons having become infected with syphilis by the mouth, an inquiry was made which led to the discovery that they had all been in the habit of smoking cigars from the same manufactory, where the finishing touches (adjusting the edges of the outside leaf, shaping the point, &c.) fell to the share of some young women suffering from specific disease of the mouth or lips. The conclusion is obvious. I am, Sirs, yours truly,

Feb. 25th, 1895.

"THE REMUNERATION OF THE RESIDENT OFFICERS IN ST. BARTHOLOMEW'S HOSPITAL."

To the Editors of THE LANCET.

SIRS,—I am sorry that my expression "a good time" should have clashed with "Fair Pay's" idea of why one tries to get on the junior staff. I quite agree with him that one does not do so with the object of having a good time. I was thinking that a year on the junior staff at St. Bartholomew's is worth four or five at a small hospital, for in the former case one learns how to work with colleagues of many and varied temperaments; in the latter, one has at the most two colleagues and often only one. To go back to the point of pay. The resident officer is in residence for six months—say, twenty-six weeks—and pays about £1 per week for his food. Therefore in twenty-six weeks he pays £26 for food.

Now, as far as I can see (my authority is the advertisements at the end of the Medical Directory), no single hospital with a school attached pays its junior residents any salary, though they feed them, and most of the appointments seem to be for only three or six months. The St. Bartholomew's junior officer is in office twelve months and in residence six. In those six he pays £26, and for his year's work he receives £25. This works out to much the same as if he got no salary and was boarded. Again, "Fair Pay" says that I know that men resident in a hospital have no opportunity of broaching the subject, nor would they be listened to. I know nothing of the kind, but I do know that when I was in residence I and one of my colleagues initiated several reforms affecting the junior staff, and that the committee were uniformly courteous and obliging, and that about a year after we left the reforms were completed. As to "R.M.O.," what does he mean by saying that I have learned that relations with other medical men are to be regulated by supply and demand in its money sense? The only meaning I can attach to his words is that the senior members of the staff have a pecuniary interest in their house physicians or surgeons not being paid more. If I have put a wrong construction on his words I will apologise in advance, but I can attach no other meaning to them. I cannot see that it is more expensive to be on the junior staff of St. Bartholomew's than that of any other hospital with a school; and not only the experience, but the

fact of having held such an appointment is invaluable. If the hospital were to pay the junior staff the full value of their services it would get off cheaply at £2000 or £3000 each, for the hospital work could simply not go on without them, but the same might be said of the cook or the porters.

I am, Sirs, yours faithfully,

AN OLD HOUSE SURGEON OF ST. BARTHOLOMEW'S.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Date of Hospital Sunday at Liverpool.

MUCH difference of opinion prevails as to the proposal to alter the date of Hospital Sunday from the second Sunday in the year to another one later in the year, when the weather may be expected to be less wintry. On the one hand it is contended that the result could not be worse and might be better, that the present Sunday is too near the Christmas and New Year's festivities, and also too soon after quarter-day and the inevitable quarterly bills; and on the other hand it is urged that the present date has been followed for twenty-four years, during which period a sum of £167,508 has been raised by the Sunday collections alone, an average of £6979 annually; and such being the happy result it would be better to leave well alone. Although the weather this year was exceptionally severe and the depression of trade worse than it has ever been before, the collections are expected to reach £6000, the unfavourable circumstances just noted having combined to raise much sympathy towards the hospitals and other medical charities. Then there is the risk of dislocating a custom of such long standing, and the fear that it may cause some permanent defaulters. The matter will be fully considered by the committee before the next anniversary comes round.

The Weather and the Distress.

Within the last few days the severity of the weather has considerably abated, and consequently the distress among the poor has been less acute. Nevertheless, the stream of benevolence still flows on, large numbers of persons being relieved, mostly in food, coals, &c. The distribution of money through the police and through the Central Relief and Charity Organisation Society prevents it being squandered on undeserving persons, of whom there must always be a large proportion in such a city as this. There are always benevolent persons ready to give alms to any applicant, and as a natural consequence there are always beggars. Organisation and charity are perfectly compatible, and no one can know better than medical men what are the evils of indiscriminate almsgiving.

Lord Chief Justice Russell.

The Lord Chief Justice is expected to preside in the Crown Court at the Assizes to be held here next month. As is well known, his lordship—first as Mr. Charles Russell and subsequently as Sir Charles Russell—was for many years attached to the Northern Circuit, and in no part of it was he better known than in Liverpool, which has been the scene of many of his forensic triumphs.

An Atrocious Murder.

At an early hour one morning last week a boy seriously wounded came out of a house and gave the alarm to some men that an old man in the same house had been murdered. The boy then fainted, and was conveyed to the Northern Hospital, where he still remains in a somewhat critical state under the care of Mr. Damer Harrison. The old man was found dead, having received very severe wounds, causing great hemorrhage. The inquest has been opened by the City Coroner and adjourned, Mr. Frank T. Paul, lecturer on medical jurisprudence, having made the examination of the body at the request of the coroner, together with the examination of the blood-stained weapons found by the police. The injured boy recovered consciousness and was able to give a description of his assailant and to identify a man whom the police arrested later as the man who assaulted him. The case has naturally attracted much excitement, but further comments must be left till after the inquest and magisterial investigation.

Feb. 26th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Egremont.

MR. SAMUEL BRAITHWAITE, J.P., has been elected first chairman of the Egremont Urban District Council. Mr. Braithwaite studied medicine at the University of Durham College of Medicine at Newcastle-upon-Tyne, and has been in practice at Egremont since 1876, in which year he succeeded Dr. Lawson. Since 1885 he has filled the post of chairman of the local board. He is surgeon to the local rifle corps, and has been lieutenant and captain; he is also member of the West Cumberland Fishery Board, and director of the Gas Company, and he was Master of the Egremont Otterhounds. He is, besides, a hard-working medical practitioner. No man in the district is held in greater esteem than the chairman of the Egremont Urban District Council.

Durham.

The University Journal, which has hitherto consisted of some six or eight pages, is to be enlarged to thirty pages, and is to be run on somewhat different lines. The College of Medicine and the College of Science at Newcastle are each to have an editorial staff, and in the journal will now appear all matters of interest and importance to those two institutions. Professor Glines, the new principal of the College of Science, has taken great interest in promoting this movement. It is hoped that this journal may become the official gazette of the University. It will be subsidised by the colleges at Durham and at Newcastle.

The Heath Surgical Scholarship.

The late president of the College of Medicine, Professor G. G. Heath, left in trust the sum of £4000 for the purpose of founding a scholarship in surgery to be awarded every second year. The value of this scholarship will be some £200, and regulations are about to be issued by the trustees. The competitors must be graduates of Durham University. It is anticipated that there will be keen competition for this valuable prize. This will be the first competition.

The Newcastle College of Medicine.

The office of secretary has become vacant by the resignation of Mr. H. Fox, R.N., and the appointment will be advertised at once. The Council of the College has recently introduced the electric light into the building, and the dissecting-room, lecture theatres, council chamber, and the corridors are now all illuminated by electricity.

The Cumberland and Westmorland Asylum.

Carlisle is a city constantly referred to in old ballads by the epithet "merry." I am reminded of this by the report of a speech made by Mr. Carrick of Scooby in his candidature for the county council. Mr. Carrick is a member of the Lunacy Committee, and in his speech made some very remarkable and interesting statements. For the last two years the recovery-rate at the Carlisle Asylum had been—for 1893 45·5 per cent., as against the average in English county and borough asylums of 39 per cent.; and for 1894, 47·9 per cent., as against 37·3. The average rate of recovery on total admissions for the last twenty-two years had been 45·7 per cent. The committee had considered the 4s. grant for pauper lunatics, and had applied to have it extended to pauper patients outside the workhouse, as in Scotland. A large building for private patients, who would otherwise have to pass through the asylum as nominal paupers, is in course of construction, and altogether Carlisle seems to be exceptionally fortunate in her treatment of lunatics and her choice of those who look after them.

Feb. 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Medico-Chirurgical Society.

THE discussion at this society on cardiac therapeutics was resumed last Wednesday before a considerably smaller audience than on the first night of the discussion. Dr. Bramwell opened in a long and somewhat too exhaustive paper on the whole subject, which occupied the first hour. He was followed by Dr. Stockman, who took a somewhat negative line of criticism. Professor Greenfield extolled in

the highest possible way the value of strophanthus as against digitalis. Dr. James Ritchie referred to various points which he had gleaned from his experience in general practice. Dr. William Russell aimed at delimiting the sphere of applicability of digitalis and strophanthus. Dr. Clouston referred to the circulatory troubles in some forms of insanity, and indicated the treatment he adopted for these cases.

Influenza in Edinburgh.

There has been quite an outbreak of influenza in epidemic form in Edinburgh. It first made its appearance some ten or twelve days ago, when the first indications of it was appeared. It is very prevalent amongst all classes. The seizures are, as a rule, quite typical, although it is at the same time accompanied by such mild cases that, occurring alone, they would be classed as febrile catarrhs. Fortunately, the lung complications do not, so far, appear to have been serious. Bronchitis is common, but pneumonia not so common or so fatal as it was a few winters ago. Still, the death-rate is high, and the number of deaths from disease of the chest is large.

Health of Edinburgh.

The death-rate last week was 36 per 1000. Out of a total death-roll of 188, 115 were due to chest diseases. Amongst the deaths were 20 cases from measles and 2 from small-pox. The intimations for the week included 683 cases of measles, 1 of small-pox, and 35 of scarlet fever.

Royal Edinburgh Asylum for the Insane.

The annual meeting of the corporation of the Royal Edinburgh Asylum for the Insane was held on Feb. 25th, Lord Provost McDonald presiding. The treasurer read a report showing that the institution had a surplus of £4717 14s. 6d. The physician superintendent (Dr. Clouston) read his report. He drew attention to the increase of general paralysis, but on the whole mental disease was not increasing. He also referred to Dr. Bruce's investigations as to the treatment of certain kinds of mental disease by thyroid feeding, and he looked forward with much confidence to the good which this plan of treatment would accomplish.

Recent Medical Appointments in Glasgow.

Certain medical appointments have recently been made in Glasgow under circumstances which have not given universal satisfaction. The University Court has instituted two new medical lectureships, and has filled them without advertising for candidates. The directors of the Western Infirmary have filled three vacancies in their staff, and, without disparaging the merits of the successful candidates, it seems to me that certain of the unsuccessful candidates had higher academical claims. It is always a pity when appointments can be made the subject of this sort of comment. It places the new holders of the posts in an unpleasant position and exposes the other gentlemen to an imputation of jealousy. The most obvious remedy would be that the meetings of the Glasgow University Court and of the board of directors of the Western Infirmary should be held in public, as is already the case as regards the meetings of the University Court of Aberdeen and those of the directors of the Royal Infirmary of Edinburgh.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Sanitary Association.

AT the annual general meeting of this association the incoming president, Dr. J. W. Moore, in the course of his address referred to the outbreak of small-pox in Dublin, and said that the public at large do not appear even yet to realise the priceless boon which vaccination has conferred upon mankind since the memorable day—May 14th, 1796—on which Edward Jenner vaccinated a peasant lad whom he failed to inoculate with small-pox two months afterwards. Before the introduction of vaccination the annual mortality from small-pox in England and Wales was at the rate of 3000 deaths in every 1,000,000 of the population. In 1891 the population was 29,081,047 and the death-rate from small-pox would represent an annual loss of some 87,000 lives. What were the actual facts? In 1890 small-pox caused only 15 deaths in England, while the annual number from this disease in the ten years 1881-90 inclusive was 1327—that is, one-eightieth only of the death-rate of pre-vaccination times. Dr. Day, resident medical

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

The Date of Hospital Sunday at Liverpool

MUCH difference of opinion prevails as to the year after the date of Hospital Sunday for the next time in the year to another one later in the year, viz. that it may be expected to be less windy. On the one side it is contended that the result could not be more successful than the present, and on the other that it would be better, that the present Sunday is too near the Christmas and New Year's festivities, and also too soon after the payment of the inevitable quarterly bills; and on the other side it is urged that the present date has been followed for nearly four years, during which period a sum of £167,581 has been raised by the Sunday collections alone, as against £100,000 annually; and such being the happy result it would be to leave well alone. Although the weather this year has been exceptionally severe and the depression of the market more than it has ever been before, the collections are expected to reach £60,000, the unfavourable circumstances having combined to raise much sympathy for the hospitals and other medical charities. The desirability of dislocating a custom of such long standing is a matter which it may cause some permanent objection to, but it will be fully considered by the committee at the next anniversary comes round.

The Weather and the Distress

The Weather and the District.

Within the last few days the severity of the has considerably abated, and consequently it is among the poor has been less acute. Numerous stream of benevolence still flows on from all persons being relieved, mostly in food, such as the tribution of money through the police and the Central Relief and Charity Organisation Society, it being squandered on undeserving persons. There are always a large proportion in this. There are always benevolent persons who aim to any applicant, and as a natural consequence are always beggars. Organisation and charity are compatible, and no one can know better this what are the evils of indiscriminate almsgiving.

Lord Chief Justice Russell.

Lord Chief Justice Russell...

The Lord Chief Justice is expected to preside at Court at the Assizes to be held here next month. Known, his lordship—first as Mr. Charles Russell—subsequently as Sir Charles Russell—was for many years to the Northern Circuit, and in no part of it so well known than in Liverpool, which has been the scene of his forensic triumphs.

An Atrocious Murder.

known than in the
of his forensic triumphs.

An Atrocious Murder.

At an early hour one morning last week a big wounded came out of a house and gave the some men that an old man in the same house murdered. The boy then fainted, and was conveyed to Northern Hospital, where he still remains in a critical state under the care of Mr. Danneberg. The old man was found dead, having received very serious internal injuries, and the cause of death was a cutting great hemorrhage. The inquest has been held by the City Coroner and adjourned. Mr. Pack has been called on for medical jurisprudence, and has examined the body at the request of the coroner, together with the medical officers of the hospital. The examination of the blood-stained weapons has been completed, and the police are now endeavoring to give a description of his assassin, and to find a man whom the police arrested later as having assaulted him. The case has naturally attracted much public interest, but further comments must be left to the press and magisterial investigation.

Feb. 25th.

officer of the Cork-street Fever Hospital, had recently stated that in not one of 488 patients suffering from small-pox, who had been admitted to the wards of that hospital from the beginning of the present outbreak in Dublin in July, 1894, up to Dec. 31st, was there the smallest evidence that revaccination had been successfully performed within twelve months previous to the development of the disease. The most noticeable feature and the strongest point in favour of vaccination is that, of the 37,000 children in the Dublin Registration District under five years of age, the vast majority of whom are known to be vaccinated, only 22 have died from small-pox during the present epidemic, and none of these 22 were protected by vaccination.

Mischiefs of Medical Charity in Dublin Hospitals.

At the recent meeting of the Dublin Branch of the British Medical Association Dr. H. C. Tweedy read a paper on the above subject. In the course of his remarks he said that the medical press had been lately dealing with the question of hospital abuse. The discussion of such a topic should be productive of good results, and it showed that the public were taking an increased interest in the hospitals, and were determined on rendering them as perfect as they might be in their general working. A comparison of the minute books of hospitals of the past with those of the present day gave striking illustrations of how in the matter of order and management hospitals had advanced during recent times. No longer now did they find the governors mere figureheads who never attended when any useful business was to be done, but turned up with unflinching certainty when some job was to be perpetrated. In other respects, also, hospital management had advanced greatly, and the hospital patient had a far better time of it than his brother or sister of days gone by. But there was a danger that the tide might overstep its natural bounds. The title of "hospital patient" had of late become abnormally elastic; the general public had been developing a tendency to avail themselves of the use of the hospitals to such an extent and in such a manner as were never contemplated by the pious intentions of the founders. In the two departments of the hospital—in the pay wards, and to a great extent in the extern dispensaries—were to be found as patients persons who could not be considered as having reasonable claims on public charity. The pay wards were originally established to meet a great want for the needs of a large class of people, such as ladies in reduced circumstances, who could not be expected to pay a large fee. But now the privilege was being usurped a good deal by a class of patients not having the most remote claim on public charity. Officers, country gentlemen and their wives, and others such as these were availing themselves of these pay wards. Their presence in the hospital at all as patients was strongly to be deprecated, for not only were they getting beds intended for a deserving and suffering class of people, but a great injustice was also inflicted on the medical and surgical staff, who had to attend them gratuitously. If pay patients were to be taken into hospitals at all their circumstances should be rigidly inquired into, and none taken except those who could not otherwise pay for the advice and nursing that they needed. Dr. Tweedy advocated the establishment of a private hospital in Dublin of the type found in Berlin and other places, and he believed that such would work with profit. The district which made up the Dublin hospital district had a population of 356,240 persons, and they found that the total number getting medical relief through the hospitals during the year was 171,897 persons, or 482 out of every 1000 of the population of the district, nearly one-half of the whole.

The Battle of the Clubs at Cork.

Large posters announced that a meeting of citizens was to be held on Thursday, Feb. 21st, for the purpose of "considering the crisis created by the doctors' circular." Members of benefit clubs and their friends were invited; for others admission was regulated by ticket. The janitors discharged their discriminating duties efficiently, and the proceedings inside were harmonious. The list of notabilities published in the morning papers showed that it was a representative meeting of the clubs and nothing more. The attempt to give the meeting the appearance of a general gathering of citizens by bringing the Mayor there to preside proved a failure. A deputation waited upon the civic authority, but he could not see his way to identifying himself with the proceedings. The chairman told his audience that they found it necessary to put on a levy of 6d. per member, but he did not add that the rich man with £800 a year paid the extra 6d. just the

same as the poor man with £1 a week, neither more nor less, which makes those of us who know wonder when the rank-and-file of the clubs will see how completely they are made cat's paws of by their wealthy brother members. Two of the speakers at the meeting happened to be paid secretaries of clubs whose income would be likely to go down if the clubs were pruned of the wealthy members. After mutual congratulations, taking the form of a vote unanimously passed commending the dignified attitude of the clubs, the attention of the meeting was directed to the decision of the magistrates in the recent snowballing case. It was felt that the student who threw the snowballs should have been more severely punished, but the lenient magistrates were held to have been terrorised by the Cork medical men!

The Norwegian barque *Mauranger* is quarantined in Valentia Harbour. Shortly after leaving Mexico the master died from yellow fever, and before the voyage commenced one of the crew died from the same affection.

The following gentlemen have been admitted Fellows of the Royal College of Surgeons in Ireland—viz., Richard B. McCausland, George R. P. Burton, and Henry Stoker.

Feb. 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The late Dr. Dujardin-Beaumetz.

GEORGE SAINFORT DUJARDIN-BEAUMETZ, whose death I chronicled in my last letter, was born in 1833 at Barcelona of French parents, and commenced his medical studies in Paris in 1853. *Interne* in 1857, M.D. Paris in 1862, then successively *chef de clinique* and (in 1870) *médecin du Bureau Central*, he took his place at the front on the declaration of war, and his bravery and devotion procured him a mention in despatches and the Cross of Chevalier of the Legion of Honour. It is stated that when in the thick of the fight at Montretout he was seen to be coolly engaged in picking up the wounded. Someone reminded him of the danger he incurred. He replied, alluding to his myopia, "Les balles! mais je ne les vois pas." Appointed physician to the Hôpital Saint Antoine in 1876 he there delivered before large audiences his *Leçons de Clinique Thérapeutique*, read since by thousands of students and practitioners. In 1882 he left Saint Antoine Hospital for Cochin (in the Rue Saint Jacques), of which hospital he remained physician until his death. There he continued his clinical teachings, set up two laboratories (therapeutics and bacteriology) which became great centres of activity, numerous pupils such as Dubief, the bacteriologist &c., being "turned out" by this Dujardin-Beaumetz school. His wide-world renown as an authority in the field of therapeutics rendered his wards a familiar rendezvous for students of this faculty and visitors, and a run up to Dujardin-Beaumetz's wards became almost as much an institution as a visit to the Salpêtrière in Charcot's time. Elected Member of the Academy of Medicine in 1880, he became a frequent speaker at the meetings of that learned assembly. As a member of the Conseil d'Hygiène his enthusiasm in sanitary reform and preventive medicine soon brought him to the front. When cholera made its unwelcome appearance in 1884 and 1892 he was the most valued counsellor of the Prefecture of Police, and the city of Paris owes him a debt of gratitude for the energy and success with which he stemmed the tide of the epidemic on those occasions. In 1892 he instituted two most precious departments—viz., the Comité Permanent and the Service des Épidémies, both of which have proved a blessing to this vast population. In 1893 the Government showed its appreciation of his worth by bestowing on him the Cross of Commander of the Legion of Honour. He was a prolific writer, his chief works being, in chronological order, "*Leçons de Clinique Thérapeutique*," "*Dictionnaire de Thérapeutique*," "*L'Hygiène Prophylactique*," "*Hygiène Alimentaire*," "*Les Plantes Médicinales*," "*Les Nouvelles Médications*," "*Le Formulaire*" (in collaboration with M. Yvon), and "*Traité des Maladies de l'Estomac*." Recently he started the publication of a library of medicine and surgical therapeutics and contributed the first volume, "*L'Art de Formuler*." He was besides the editor-in-chief of the *Bulletin de Thérapeutique*, and contributed countless valuable reports to the Conseil d'Hygiène on various sanitary questions as they cropped up. He was also the founder and Honorary President of the Société de Médecine et de Chirurgie

Pratiques. Some idea of his intellectual activity may be gathered from the fact that on the day of his death (Feb. 15th) a paper dictated by him appeared in his journal, the *Bulletin de Thérapeutique*. It was always a matter of regret and surprise that the efforts he made to enter the conservative precincts of the Faculty as Professor remained fruitless. Instead, however, of retiring in disgust he manfully set about instituting a series of independent lectures, with the result that his works became more widely read than those of any professor of therapeutics at the exclusive faculty of which he would have been one of the chief ornaments. He was adored by his pupils, and his cheery presence in his wards was ever welcomed by his poor patients. His health had for the last few years been far from satisfactory, but in September, 1893, he reappeared apparently quite restored after having undergone an operation (laparotomy) at the hands of Professor Terrier. During the respite of seventeen months he continued to work, and when at last constrained to leave Paris he repaired to the south; his habitual cheerfulness of disposition never left him, and he died the same bright being he always had been. In the late Dr. Dujardin-Beaumetz we may salute in all sincerity a true searcher after truth, the students' friend, and an *homme de bien*.

Death of M. Alphonse Guérin.

Yet another ornament of the profession has just disappeared in the person of Alphonse Guérin. The life work of this distinguished surgeon deserves more than a passing notice. I, therefore, make no apology for deferring until next week an account of his career, which will be read with interest by all students of surgical progress. Suffice it to say that he was buried with military honours yesterday at the Church of St. Pierre de Chaillot, the pall-bearers being Dr. Empis (President of the Academy of Medicine), Dr. Anger (President of the Société de Chirurgie), Dr. Bergeron (Permanent Secretary of the Academy of Medicine), Dr. Peyron (Director of the Assistance Publique), and Drs. Merklen and Lucas-Championnière. After the ceremony the remains were conveyed, *en route* for Brittany, to the Gare Montparnasse, where several speeches were delivered.

Sterilisation of Water.

M. Frémont¹ has succeeded in proving experimentally that water maintained for twenty minutes at a temperature of 80° C. loses all the pathogenic micro-organisms it may have contained without being deprived of its gases and without involving any precipitation of the contained salts. It is stated that the flavour of the water is in nowise modified by the process—a most important consideration.

Which is, Ophthalmologically, the best Artificial Light?

Dr. Trousseau, surgeon to the Quinze-Vingts Eye Hospital, gives² the preference for innocuity to incandescent electric light, and assigns the second place to petroleum lamps, which may advantageously be employed for ordinary purposes. He condemns *in toto* the light yielded by oil, and more particularly that given by candles. The gas-jet is the most hurtful to the eye, its only recommendation being its convenience.

Feb. 26th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Leyden on Hospitals for Consumption.

At a meeting of the National-Verein für Hebung der Volksgesundheit (National Health Association), Professor Leyden read a paper on Hospitals for Consumption. The meeting was well attended, and among the distinguished guests were the Chancellor, Prince Hohenlohe, and several gentlemen representing the Cabinet. Professor Leyden first mentioned the fact that in Germany 120,000, and in Berlin not less than 20,000, people suffered from phthisis, and one-seventh of all deaths in Germany is attributed to tuberculosis. The poor sufferers either remained at home, where they do not obtain the necessary care, or are sent to the general hospitals, which are not fitted for this class of patient, and where the phthisical have to be dismissed now and again too early, when their room is wanted for more urgent cases. What is wanted in Berlin, Professor Leyden showed, is special hospitals where poorer sufferers can be treated prin-

cipally from the hygienic and dietetic point of view, the existing institutions being fitted by their prices only for the more wealthy class. Professor Leyden alluded to England, where the first consumption hospital was opened in 1814, and where now more than 4000 phthisical people can be attended in special institutions. In Germany there exist only very few of these hospitals, one in Malchow, near Berlin, belonging to the municipality of the metropolis, where eighty patients can be received; one in the neighbourhood of Frankfurt; and two small houses in Andreasberg in the Hartz Mountains and in Görbersdorf, both of which are maintained by charitable contributions. Professor Leyden hoped, however, that matters would soon be changed for the better. A rich banker had in what he (Professor Leyden) termed the "tuberculin era" made a donation of £50,000 to the city of Berlin for the construction of a hospital where the tuberculin treatment should be adopted. When tuberculin appeared to be a failure, the money was not used according to the will of the donor, and now the town council intends, Professor Leyden understands, to spend this sum upon a hospital where the sufferers will not be treated by Koch's remedy, but by hygienic measures. If only patients in the first stages of the illness were received an average sojourn of three months would suffice. Professor Leyden hoped that not only would the hospital be opened to the indigent, but also to the middle classes, who were unable to pay the high pension prices required in the existing private establishments. He closed his address with the remark that a southern climate and the air of the mountains were a great advantage, but not a strict necessity for the phthisical; and that they could be cured if they had good food, a well-ventilated room, and plenty of fresh air. After the discussion a committee was elected to take practical measures to propagate the idea of the construction of hospitals for phthisical patients.

Accidents and Ambulance Organisation in Berlin.

In Berlin the ambulance organisation has been, till recently, very deficient. If, for instance, a person is run over in the street by a carriage the proceedings are as follows. At first a great many people assemble round the victim to give their opinion of the matter. Then several run to the houses of the surgeons in the neighbourhood, who probably are not at home. Finally, a policeman with the assistance of some of the more intelligent of the crowd place the injured man into an ordinary four-wheeler and take him to a hospital. Very often this want of ambulance organisation has led to serious results, numerous examples of which I could narrate. For night accidents, it is true, there are the Sanitäts-Wachen dressing-rooms in several quarters of the town, where from 10 P.M. to 6 A.M. a medical man and an assistant are on duty. These are maintained by the contributions of the inhabitants of the quarter, and their medical officers have to attend casualties in the waiting-room or to go into the houses if their help is wanted. Their necessity has been often disputed by the profession, for in the night medical men are usually at home and can be found without difficulty. Besides, very often people go to the Sanitäts-Wachen who have not met with an accident, but have some other complaint for which they hope to be treated free of charge. As in the night all the manufactories are closed the sufferers from really grave accidents derive no advantage from these waiting-rooms, and the *habitués* are principally rowdies who have been wounded in night rows. Notwithstanding all this, the Sanitäts-Wachen have existed nearly twenty years, and now get an annual subvention from the town council of 40,000 marks. They are rather insufficiently furnished with litters and have no ambulance carriages; but not even the great general hospitals possess ambulance carriages. The only ambulance carriages that exist belong to private undertakers, who also transport sick people and are in emergency cases difficult to obtain. During the past year a great improvement has been made in this matter by a private society. This society has established at different points of the town Unfall-Stationen (accident stations). There are four principal stations and eight branch stations. At the principal stations there are newly constructed horse ambulances which are ready to start immediately in case of alarm; the principal stations are connected with accident wards of thirty or forty beds, where the injured can be attended till they recover. The branch stations consist of a dressing-room with the necessary instruments and dressing materials, and a room with one or

¹ Journal de Médecine de Paris, Feb. 17th.

² France Médicale, Feb. 15th.

two beds where the wounded can rest some time. At all the stations surgeons and assistants are on duty day and night. They have telephonic communication, so that in cases of accidents the ambulances and surgeons can easily be called. The new organisation has already been found to be of the greatest practical use.

Feb. 26th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Closing of the Universities.

DR. BACCELLI is to be congratulated on his academic *coup d'état*. No man is a greater friend of the student than his Excellency, but there are limits even to his forbearance, and these have long ago been reached. The undergraduates of Rome, acting in a spirit of solidarity with their brethren of Naples, held a "sympathy meeting" in the quadrangle of the *Sapienza* and denounced his Excellency's measures in language quite unbecoming the scene and its subject. Even this might have been connived at, but when from words the speakers and their audience proceeded to riot the *carabinieri*, in behalf of public order, had to intervene and tried to enter the quadrangle. The students at once assumed the defensive, and by dint of numbers bore back the invading force and shut the great doors in its face. This success, however, was but short-lived. Eight of the ringleaders, by order of the *Senatus Academicus*, were next day suspended from their studies, but without appreciable effect in restoring calm. A mass meeting of some 800 students was held in the Colosseum, where the proceedings recalled the violence and tumult of the gladiatorial arena rather than the decorum of academic discussion, and again the *carabineers* had to interpose. The struggle that ensued was a determined one; three of the most turbulent of the students were arrested and subsequently recaptured by their friends, till the *Senatus Academicus*, impotent to restore order, appealed to the Minister of Public Instruction, at whose instance the University was closed for the year. Meanwhile the epidemic of insubordination has spread throughout the kingdom, and even such staid and dignified seats of learning as the *Istituto di Studi Superiori* at Florence have been beset by the mutinous spirit. It is, indeed, a declared war between the *Burschenschaft* of Italy and the academic authorities, and nothing short of disaster would ensue if the former were victorious. Of that, however, there is no danger. Dr. Baccelli, one of the most genial, is also one of the most resolute of men, and the interests of education in general and medical education in particular are too dear to him to tolerate for an instant the postponement of either to undergraduate importunities. When tranquillity has been restored and the young mutineers have quietly resumed their work the commencement of a new era in university life will be felt. Dr. Baccelli's academic policy will have been advanced several stages towards its embodiment in the Statute-book, and a salutary reform will have begun in the academic system of Italy. High time is it that such should become *un fait accompli*. For the thirty millions of Italians there are twenty-one universities. The higher education is so cheap and graduation so easy that the country swarms with unemployed professional men too proud to enter a business, but not too proud to become political agitators, in the press or on the platform. The commercial and industrial life of Italy is thus impoverished for the repletion of a pseudo-professional class, and politics are infected with place-hunters too numerous and too clamorous to make sober, steady legislation possible. Of all this no man is more cognisant than Dr. Baccelli, and he has long been maturing innovations which shall restore the healthier academic life of the Renaissance. His views on this subject, however, have too often been put before the readers of THE LANCET to warrant recapitulation here.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Cholera.

CASES of cholera are on the increase in Constantinople and its suburbs. From 15 to 25 cases are recorded daily, the mortality ranging from 3 to 8. The disease has disappeared from the other parts of the country with one exception, but

fresh cases are reported from Adalia, in the province of Koniah. The Board of Health has taken every trouble and care for the protection of the health of the capital and of all the provinces, and the Admiralty is sending gunboats to the lazarettos of Tonzla, a small port on the Asiatic coast of Marmora, and Kavak, at the mouth of the Black Sea, to watch over the vessels undergoing quarantine in those two lazarettos. The Servian Board of Health has decreed a quarantine of five days on travellers arriving from Constantinople; and a recent telegram from Sofia says that the Bulgarian authorities, foreseeing that in consequence of the imposition of five days' quarantine at Tobataldja on arrivals from Constantinople travellers will take the sea route, have decreed medical inspection with disinfection of luggage at Varna and Bourgas, and eventually a term of quarantine against travellers coming direct from Constantinople.

Small-pox.

The bulletin published in the *Gazette Médicale d'Orient* registers 277 deaths in Constantinople between Jan. 21st and 28th. Of these, thirty-three were due to small-pox. The disease has already spread all over the city irrespectively of class. The Government has been very energetic in combating the spread of the disease, and has supplied vaccine to a number of public and military schools. Most of the vaccine now used in the country is prepared at the Imperial School of Medicine. Free dispensaries are opened in the poor and crowded districts. The epidemic is unfortunately raging in many provinces at the same time.

The Sultan and Phthisis.

The Sultan has charged his personal physician, Dr. Mavrogény Pasha, to bring before the Imperial Society of Medicine the following question for discussion: "Is pulmonary tuberculosis contagious; if so, to what degree is it contagious?" The society, after expressing its thanks to the Sovereign, entered the question into the order of the day. The discussion will commence within a week.

New Buildings.

The ceremony of laying the foundation-stone of the Imperial School of Medicine at Haïdar Pasha, Constantinople, took place on the 12th ult. on the occasion of the anniversary of the Sultan's birthday. The Hall for Surgical Operations, built in the park of the Military Hospital at Haïdar Pasha, was also inaugurated on the same day.

Feb. 19th.

Obituary.

WILLIAM HENRY DAWSON, M.D. DURH.,
M.R.C.S. ENG., L.S.A.

DR. WILLIAM HENRY DAWSON, whose sudden death from heart disease was recorded in THE LANCET of Feb. 16th, was the son of Mr. R. H. Dawson, an Exeter merchant, and was born in that city on Nov. 17th, 1837. Dr. Dawson was educated at Christ's Hospital, which he left well up on the list of "Grecians," and subsequently served his apprenticeship with Mr. E. P. Pridham, a well-known surgeon of Exeter and a pupil of Abernethy. At St. Bartholomew's Hospital he attained some distinction among the pupils of his time, gaining, among other prizes, that in anatomy. Immediately on taking his diploma he went to Malvern as assistant to the late Mervin Coates, who at once recognised his ability, and it was with his sanction that after a few years he commenced to practise independently in the town, where he continued for thirty-five years. From the first he met with marked success, and was appointed surgeon to the Malvern Lying-in Hospital, which led to a large development in his midwifery practice. He was one of the prime movers in establishing the Cottage Hospital, and became its first superintendent surgeon, a position he held till within a few years of his death. He was also one of the medical officers to the dispensary, and for the past three years had been medical officer of health to the district, offices which he discharged with great assiduity and distinction. To various charitable institutions he gave valuable assistance. He was one of the first to recognise the importance of the Volunteer movement, and was for a considerable period a member of the local rifle corps. Dr. Dawson had a large private practice, and his skill in surgery had more than local renown. To the poor he was always the

kindest of friends, rendering them professional and other assistance, often when his only reward could be their gratitude. By his removal the town has been deprived of a zealous and most efficient public servant, while a large circle of friends will mourn the loss of one who was regarded by all who knew him as a man just and upright in all his dealings. The very general sorrow felt at his death cannot but be a solace to Mrs. Dawson and her family in their hour of heavy bereavement.

HENRY MONTAGU CHAMPNEYS, F.R.C.S. ENG., L.S.A.

HENRY MONTAGU CHAMPNEYS was a son of the Rev. Charles Champneys, Minor Canon of Windsor, Rector of St. Botolph's in the City. He was born in 1818 at Bow in Middlesex, and studied at Guy's Hospital. He became M.R.C.S. in 1841 and L.S.A. in 1844, and was elected F.R.C.S. in 1858 at the instance of Mr. Cooper and Sir Henry Pitman. He practised first at Slough, where he was surgeon to the police and Great Western Railway Provident Society. There being no hospital at that time between Reading and London, and the railway between Slough and Windsor being in course of construction, severe surgical cases were treated at the Eton Union, to which Mr. Champneys was surgeon. In 1861 he went to Battle in Sussex, and in 1867 moved to Penge, where he remained in practice till the time of his death, after a few hours' illness, on Feb. 11th. The cause of death was angina pectoris and syncope. A few years ago he was elected to the Court of Assistants of the Apothecaries' Company. One of the most interesting episodes of Mr. Champneys' earlier life was the trial of the Quaker, John Tawell, who was eventually hanged for the murder of Sarah Hart by prussic acid poisoning. Mr. Champneys was first called to the woman at Slough in January, 1845, and throughout the subsequent trial his medical evidence was of no little importance. The case will be remembered from the fact that the defence put forward the theory that some apple pips found in the stomach were sufficient to account for the presence of the amount of prussic acid found.

JOHN ROSE, M.R.C.S. ENG., L.S.A.

MR. ROSE was one of the oldest—perhaps the oldest—practitioner in Islington. He was in his early days a pupil of the late Mr. Freeman of Spring-gardens, and so came into professional contact with historical persons and historical members of the profession. He commenced practice in the neighbourhood of Liverpool-road, later removing to Canonbury-lane, and finally to Parkhurst-road, where he died. He took the licence of the Society of Apothecaries in 1839 and eight years afterwards the Membership of the Royal College of Surgeons of England. Mr. Rose was a sound practitioner and an upright and God-fearing man. He was greatly respected by a large number of friends and patients. His health had been failing for some time with renal and other troubles, from which, however, he was partly recovering when the prolonged and intense frost caused congestion of the lungs and quickly extinguished his life. Mr. Rose, who was a bachelor, was in his eighty-second year at the time of his death.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in the under-mentioned subjects:—

Surgery.—L. M. Breton, St. Thomas's Hospital; W. J. Gillespie, St. Bartholomew's Hospital; D. W. Jones, Charing-cross Hospital; S. E. Price, London Hospital; H. Roberts, St. Mary's Hospital; W. Sutcliffe, Birmingham; M. M. Townsend, King's College Hospital.

Medicine, Forensic Medicine, and Midwifery.—A. F. Blake, London Hospital; W. Mettam, Sheffield; H. H. Thomas, Charing-cross Hospital.

Medicine and Forensic Medicine.—W. E. Bremner, King's College; R. Keatinge, London Hospital.

Medicine and Midwifery.—H. G. C. Hardwick, St. Thomas's Hospital.

Medicine.—H. Roberts, St. Mary's Hospital.

Forensic Medicine and Midwifery.—S. S. Wallis, Guy's Hospital.

Forensic Medicine.—J. C. G. Reed, Guy's Hospital; and G. Lowsley, St. Bartholomew's Hospital.

Midwifery.—A. H. Wade, St. Bartholomew's Hospital.

To Messrs. Jones, Keatinge, Mettam, Price, Roberts, and Sutcliffe was granted the diploma of the society.

UNIVERSITY OF EDINBURGH.—The degrees of M.B., C.M. were conferred on the following six gentlemen on Jan. 26th:—

W. G. Alexander, Selkirk; G. H. Drury, Halifax; Malcolm McLarty, Edinburgh; A. J. M. Paget, London; Thomas Roberts, Carnarvon, North Wales; and J. M. Taylor, Edinburgh.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following gentlemen have obtained the Diploma in State Medicine:—

George O. E. Burditt and Henry Stoker.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.—The following gentlemen, having passed the necessary examination, have been admitted Fellows of the College:—

Richard Bolton McCausland, Dublin; George Rooke Penrose Burton, Westmorland; and Henry Stoker, Dublin.

NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.—The Hon. W. F. D. Smith, M.P., will preside at the annual dinner of the above association on Tuesday, April 23rd, at the Grand Hotel. The claims upon the funds of the association exceed considerably the amount of its available income, and an earnest appeal is made for public support.

PRESENTATION.—Dr. Thomas Jackson of Whitehaven, a zealous supporter of the temperance cause in Cumberland, and well known to all adherents of the movement in the North of England both as a medical man and as a citizen, has just been presented by his fellow-townsmen, in recognition of his steadfast and valuable services in the cause, with a complete edition of the Encyclopædia Britannica and bookcase, accompanied by a solid silver tea service and an album containing the names of the subscribers.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The fifth meeting of the session was held on Feb. 13th. Mr. A. W. Prichard and Dr. Edgeworth brought before the society a case of intestinal obstruction from congenital malformation; Dr. Harrison, Mr. Munro Smith, and Dr. Aust Lawrence discussed the case. Dr. J. E. Prichard read a case of unusual development of intestine, and also showed specimens of an anencephalous monster, and horseshoe kidney; Dr. Harrison, Dr. Aust Lawrence, Mr. Ewens, and Dr. J. G. Swayne discussed the cases. Dr. Aust Lawrence read a paper on some cases of inversion of the uterus; Dr. J. G. Swayne, Mr. Paul Bush, Dr. W. C. Swayne, Dr. Steele, and Dr. Harrison spoke on the subject. Mr. Ewens described a case of multilocular parovarian cysts of both ovaries, in which he had performed a successful operation; Mr. Morton, Dr. W. C. Swayne, and Dr. J. G. Swayne commented on the case.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 20th, Dr. Tew, President, being in the chair. Dr. Watson read a paper, illustrated by drawings and lantern slide photographs, on the Calcareous Corpuscles of Tapeworms: What are they? He gave the history of the subject and alluded to the views of von Siebold, Goodsir, and others. The bodies were invariably present in tapeworms and echinococci, but could not be studied in the tissues of the *conurus cerebralis* from the sheep. Here they could be seen as round or oval bodies with a capsule and well-defined nucleus, which latter might be divided into two or more parts. After discussing the views of various writers, the speaker expressed the opinion that the bodies might be parasitic protozoa. He referred to the bodies he had seen undergoing fission as evidence of this, and to their apparent independence of the tissues in which they lay. In some respects they resembled coccidia, but at present they could not be classified in any known species. The President and Dr. Ransom having made some remarks, Dr. Cattle showed on the screen some drawings and photographs of rabbit's coccidia and of cancer bodies. With regard to the bodies described by Dr. Watson he remarked that they did not appear to have an intra-cellular stage, as always appeared to be the case with the growing forms of parasitic protozoa, and further that no development appeared to have been observed in them after their removal from the body. Mr. Chicken showed a Pedunculated Tumour removed by means of the écorseur from the upper part of the rectum of a woman of middle age. Dr. Wm. Ransom showed microscopic sections of Hypertrophic Cirrhosis of the Liver and Spindle-celled Sarcoma of the Kidney.

LITERARY INTELLIGENCE.—We are asked to announce that with the first number of the thirteenth volume of the *Bristol Medico-Chirurgical Journal*, which will appear this month, an addition will be made to the editorial staff of the journal. Dr. Bertram Rogers of 11, York place, Clifton, will act as editorial secretary.—The Secretary of State for India has a limited number of copies of the "Nature of Cholera," by the late Dr. Bellew, which he will be glad to distribute amongst such medical institutions and hospitals as may desire to have them. Applications should be addressed to the Under Secretary of State for India, India Office, London, S.W.

ROYAL METEOROLOGICAL SOCIETY.—The usual monthly meeting of this society was held on Feb. 20th at the Institution of Civil Engineers, 25 Great George-street, S.W., Mr. R. Inwards, F.R.A.S., President, being in the chair. Mr. W. Marriott gave an account of the thunderstorm and squall which burst over London so suddenly on the morning of Jan. 23rd. It appears that this storm passed across England in a south-east-easterly direction at the rate of about forty-seven miles an hour, being over Northumberland at 4 A.M., and reaching the English Channel by 11 A.M. Thunder was first heard in the vicinity of Leeds, and accompanied the storm in its progress across the country. One of the most remarkable features of the storm was the sudden increase in the force of the wind, for in London it rose almost at one bound from nearly a calm to a velocity of thirty-six miles an hour. This sudden increase of wind caused considerable damage, and at Bramley, near Guildford, twenty-eight trees were blown down along a track 1860 yards in length.

SANITARY ASSURANCE ASSOCIATION.—The fourteenth annual meeting of the Sanitary Assurance Association was held at the offices of the association, 5, Argyll-place, W., on Monday, Feb. 11th, Mr. Henry Rutherford, barrister-at-law, in the chair. Mr. Joseph Hadley, secretary, read the annual report, which stated that the work of the association continued to be carried on in accordance with the plan initiated by it in 1881. County councils, schools, and other authorities continued to seek the services of the association and to act on the advice given in the reports, plans, and specifications of works furnished by its officers. The council stated that, while recognising to the full the excellent work done by the local authorities in carrying out the Public Health Acts, nevertheless, bearing in mind the deadly nature of sewer air and the suffering still ensuing from unhealthy conditions, they feel that such an organisation as the Sanitary Assurance Association continues to be indispensable. The income for the year had been £404, and after meeting all liabilities a balance was carried forward. On the motion of the chairman, seconded by Dr. K. Macleod and supported by Dr. Willoughby and Mr. Mark H. Judge, the report was unanimously adopted. Mr. Roger Smith, Professor of Architecture at University College, and Mr. Henry Rutherford were re-elected members of the executive committee. Dr. K. Macleod was elected president of the association for the year; and Sir Joseph Fayrer, F.R.S., Surgeon-General Cornish, and Mr. Andrew Stirling were elected vice-presidents.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Frozen Meat.

Mr. T. D. SULLIVAN has given notice of the following question for a day next week—viz., to ask the President of the Board of Agriculture whether, previously to the slaughter in Australia and other places of sheep and cattle whose flesh is converted into frozen meat and sent to this country for human food, they are examined by competent inspectors, with a view to ensure that no animals suffering from disease shall be used for that purpose.

The Superannuation of Poor-law Officers.

Mr. Walter Long, who held office under the late Administration as Parliamentary Secretary to the Local Government Board, has introduced into the House of Commons a measure to provide superannuation allowances for Poor-law officers. At present these officers possess an equitable statutory claim to a superannuation allowance after not less than ten years' service upon becoming incapacitated from the performance of their duties by reason of permanent mental or bodily infirmity or of old age. The allowance, however, is dependent upon the discretion of boards of guardians, and while during the

last thirty years the majority of boards have recognised the claims of the officers there have been many cases where grants have been refused. Mr. Long's Bill proposes that in return for a percentage contribution from their salary and emoluments every Poor-law officer shall be entitled to a superannuation allowance when he becomes incapable of discharging the duties of his office by reason of permanent infirmity of mind or body or of old age. The Bill also proposes to give power to the boards of guardians to require an officer who has attained the age of sixty-five years to retire when they are of opinion that his retirement is desirable in the interests of the public service.

The Pistols Bill.

We have repeatedly called attention to the unsatisfactory state of the law with regard to the sale and use of pistols and toy firearms, and several attempts to deal with the matter have been made both in the House of Commons and in the Upper Chamber. In 1893 Mr. Asquith brought in a Bill which embraced suggestions frequently advanced in THE LANCET, and last year Lord Stanley of Alderley proposed a measure making the sale of toy pistols illegal. This Bill was so mauled in committee that the noble Lord disclaimed responsibility for the changes. On Wednesday last Lord Carmarthen introduced a Bill into the Commons which is virtually the proposed measure of Lord Stanley as amended. With the object of preventing the sale of toy pistols a clause has been inserted providing that a licence of £1 shall be required from vendors of pistols. The motion for the second reading was carried by 204 against 85 votes.

The Influenza.

Replying to a question by Mr. Aird in the House of Commons on Tuesday last, Mr. Shaw-Lefevre said the inquiries instituted by the Local Government Board in 1890-91 and in 1892-93 dealt with the epidemic of influenza from a statistical and general aspect, and with its clinical and bacteriological features. The results of the inquiry were embodied in two large reports and presented to Parliament. In 1892 a memorandum was issued by the Board suggesting advisable prophylactic measures, and there was no reason to vary those suggestions. With regard to the recirculation of the memorandum, not only in the metropolis but also in the districts where the epidemic prevailed, the President of the Local Government Board said he would see what could be done in the matter.

Accidents in Industrial Employments.

It is the intention of the Government to introduce another Bill this session to make provision for public inquiry in regard to fatal accidents occurring in industrial employments in Scotland.

The Walthamstow Inquiry.

On the motion of Mr. George Russell, an address has been presented to Her Majesty for copies of the report of the Commissioner appointed by the Home Secretary to inquire into allegations made regarding the treatment of children in the St. John's Industrial School for Roman Catholic boys at Walthamstow, of the evidence taken, and of the letter addressed to the managers of the school by the Home Secretary at the close of the inquiry.

The Public Health Acts.

Sir Albert Rollit has prepared a Bill to amend the Public Health Acts with respect to sewers.

HOUSE OF COMMONS.

THURSDAY, FEB. 28TH.

A New Mines Bill.

Mr. John Ellis asked the Secretary of State for the Home Department whether, having regard to the proved danger to life of the manner in which shot-firing is now carried on in many coal mines, and the investigation, report, and recommendations of the Royal Commission on Explosions from Coal Dust in Mines, he is prepared to introduce and press forward a Bill dealing with the subject.—Mr. Asquith said he had prepared a Bill dealing with fiery and dusty mines, and with the precautions to be taken in firing shots in mines. The recommendations of the Royal Commission had been attended to in framing the Bill, and he hoped to introduce the measure on an early day.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BAUCHOP, W. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Public Vaccinator for the Lumsden District, New Zealand.

BOBART, A. O., M.B., Ch.B. Melb., has been appointed a Surgeon to Her Majesty's Fleet, Victoria, Australia.

BYERS, ALFRED, M.B., Ch.B. Vict., B.S. Lond., has been appointed Junior Resident Medical Officer to the General Hospital for Sick Children, Pendlebury, Manchester.

DENNIS, O. A., L.D.S.R.C.S. Irel., has been reappointed Honorary Dental Surgeon to the Nottingham General Dispensary.

FAVELL, RICHARD, M.R.C.S., has been reappointed Surgeon to the Jessop Hospital for Women, Sheffield.

GERATY, THOS., L.R.C.P. Irel., M.R.C.S. Eng., has been reappointed Honorary Consulting Surgeon to the Nottingham General Dispensary.

GIBLIN, E. O., M.D. Aberd., M.R.C.S. Eng., has been appointed Surgeon-Major to the Tasmanian Rifle Regiment, Tasmania.

GRACE, H., L.R.C.P. Lond., L.R.C.S., L.M., has been reappointed Medical Officer of Health for Kingswood.

GRAHAM, A. W., M.B., L.R.C.P. Lond., M.R.C.S., has been appointed an Additional Public Vaccinator for the District of Rivoton, New Zealand.

GRANT, A. A. C., M.B., M.S. Glasg., has been appointed House Surgeon to the Maternity Hospital, Glasgow.

HINCKELL, JAS. S., M.D. Camb., M.R.C.S., has been appointed Assistant Medical Officer to the Suffolk General Hospital.

HOGG, R. B., M.R.C.S. Eng., has been appointed Public Vaccinator for the Timaru District, New Zealand.

HOWATSON, C. W., M.B., C.M. Edin., has been appointed Medical Officer for Danblane Prison, vice Brown, resigned.

JACOBSON, G. OSCAR, M.R.C.S., L.R.C.P., has been appointed Medical Officer and Public Vaccinator for the Pembridge District of the Kingston Union, vice R. C. Williams, resigned.

KENDALL, H. W. M., M.R.C.S. Eng., has been appointed Honorary Surgeon to the First Westland Rifle Volunteers, New Zealand.

McBRARTY, JAS., L.F.P.S. Glasg., has been appointed Public Vaccinator for the District of Brunner, New Zealand.

MACDONALD, THOS., M.B., C.M. Edin., has been appointed Parochial Medical Officer for Kiltarity.

MACDONNELL, JAS. A., M.B., C.M. Aberd., has been appointed Public Vaccinator for the Buller District, New Zealand.

MARTIN, J. W., M.D., M.Ch. Irel., has been reappointed Honorary Medical Officer to the Jessop Hospital for Women, Sheffield.

MILES, G. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Superintendent to the Hospital for the Insane at Newcastle, New South Wales, and also Health Officer for the Port of Newcastle, vice Ross.

MILLARD, R. J., M.B., Ch.M. Syd., has been appointed Medical Officer to the Hospital for the Insane at Callan Park, New South Wales.

MENCHIN, E. J., L.R.C.P. Lond., L.R.C.S. Irel., has been appointed a Public Vaccinator in South Australia.

MORRICK, GEORGE GAVIN, M.A., M.D. Camb., M.R.C.P., has been appointed Physician to the Salisbury Infirmary.

NIX, H. W., M.B. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer of the Pillbara District and also Public Vaccinator for the Urban and Suburban Districts of Marble Bar, and the Rural District of Pillbara, Western Australia.

PARKINSON, WALTER GEORGE, M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Hospital for Women and Children, Leeds.

PIERCE, WM., M.D., L.R.C.S. Irel., has been appointed Assistant Health Officer at Watson's Bay, New South Wales, vice Sibbey, retired.

PROUDFOOT, R., M.B., M.C. Edin., has been appointed Resident Medical Officer at the Prince Alfred Hospital, Sydney, New South Wales.

PRYCE, F. D., M.R.C.S., has been reappointed Honorary Consulting Surgeon to the Nottingham General Dispensary.

ROBIN, V. J. R., L.R.C.P. Lond., has been appointed Surgeon to the Port Douglas Hospital, Queensland, vice Bowser.

ROSS, C., M.D. Syd., M.B., Ch.M. Edin., has been appointed Medical Superintendent of the New Hospital for the Insane at Kenmore, near Goulburn, New South Wales.

TAYLOR, G. H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Superintendent at the Coast Hospital at Little Bay, near Sydney, New South Wales.

TAYLOR, SHEPHERD THOMAS, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer of Health to the Chingford Urban District Council.

TEALE, J. W., M.A. Oxon., F.R.C.S., C.M., has been appointed Honorary Consulting Surgeon to the Royal North Sea Bathing Infirmary, Scarborough, vice Cooke.

THOMSON, JOHN B., M.B., C.M. Edin., has been appointed Public Vaccinator for the District of Arrow, New Zealand.

TRUMAN, E. B., M.D. St. And., M.R.C.S., has been reappointed Honorary Consulting Surgeon to the Nottingham General Dispensary.

WEBSTER, F. R., M.R.C.S., has been appointed Honorary Consulting Surgeon to the St. Albans Hospital and Dispensary.

WELLS, T. P. G., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Honorary Medical Officer to the St. Albans Hospital and Dispensary.

WHITE, G. B., M.R.C.S., has been reappointed Honorary Consulting Surgeon to the Nottingham General Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician, for six months. Board and residence and allowance for washing provided. Applications to the Secretary, office, 24, Finsbury-circus, E.C.

Births, Marriages, and Deaths.

BIRTHS.

HENDLEY.—On Feb. 23rd, at Dharmasala, Punjab, India, the wife of Surgeon-Captain Harold Hendley, I.M.S., D.P.H., Civil Surgeon, of a daughter. (By telegram.)

JESSOP.—On Feb. 24th, at Fitzjohn's-avenue, N.W., the wife of Edward Jessop, M.R.C.S., L.R.C.P., of a daughter.

STEVENS.—On Feb. 27th, at Springfield, Tulsa-hill, S.W., the wife of A. B. Stevens, M.B. Oxon., of a daughter.

WILLIAMSON.—On Feb. 22nd, at Eldon-square, Newcastle-on-Tyne, the wife of G. E. Williamson, M.A., F.R.C.S., of twin sons; one was stillborn.

WRIGHT.—On Feb. 22nd, at Leinster-square, W., the wife of Dudley D.A. Wright, Esq., M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

ATTERBURY—HILL.—On Jan. 2nd, 1895, at Napier Cathedral, Hawke's Bay, New Zealand, Walter Atterbury, M.D., of Akaroa, Canterbury, to Ethel Jane Foster, third daughter of Thomas Hill, late Collector of Customs, Auckland.

FORSYTH—ACKERMANN.—On Feb. 26th, 1895, at the Parish Church, St. Austell, Cornwall, by the Vicar, the Rev. Canon Hammond, LL.B., Charles Forsyth, M.D., and B.S., of Middleton, Manchester, to Beatrice Mauel, youngest daughter of the late George Ackermann, London, and of Mrs. Ackermann, Brisbane House, St. Austell.

GROSE—BALSDON.—On Feb. 26th, at Wear Gifford, John Sobey Grose, M.R.C.S. Eng., L.R.C.P. Lond., of Bideford, to Mabel E. Balsdon, of Wear Gifford.

HANNAN—CLAYTON.—On Feb. 23rd, at St. John's, Southwick-crescent, W., by the Rev. C. F. Clayton, M.A., assisted by the Rev. W. C. Heaton, M.A., Vicar of Holy Trinity, Gough-square, and the Rev. A. P. Clayton, M.A., Vicar of Holy Trinity, Ventnor, I.W., Francis J. Hannan, M.D., 29, Camden-road, Regent-park, N.W., to Ada, youngest daughter of the late S. W. Clayton, Esq., and of Mrs. Clayton, Eastfield, Hyde, I.W.

HILLIER—SHUTTLEWORTH.—On Feb. 26th, at Dallington Church, by the Rev. P. Ward, Curate of St. Mary's, East Moulsey, assisted by the Rev. T. C. Beasley, M.A., Vicar, Sidney Hillier, M.D. Edin., of Stowmarket, Suffolk, to Mary Ethel, youngest daughter of Joseph Shuttleworth, of Elmleigh, Dallington, Northamptonshire.

DEATHS.

BULTEEL.—On Feb. 21st, at Looseleigh, Devon, James Courtney Bulteel, M.D. Edin., in his 86th year.

CLARENDON-SMITH.—On Feb. 23rd, at Royal-crescent, W., Henry Clarendon-Smith, M.R.C.S., aged 86 years.

CLARKE.—On Feb. 23rd, suddenly, while on a visit at Leura, Toorak, Melbourne, Surgeon-General Jno. Jas. Clarke, of Vernon-terrace, Brighton. (By cable.)

CREIGHTON.—On Feb. 21st, at Derryree House, Lisnaken, Ireland, Robert Creighton, M.R.C.S., J.P., Deputy-Inspector-General, R.N., retired, aged 68 years.

DOUGHTY.—On Feb. 24th, at his residence, Philbeach-gardens, S.W., Edward Davidson Doughty, M.R.C.S., aged 83 years.

GEORGE.—On Feb. 24th, at Eastfield House, Horncastle, Lincolnshire, Hugh George, M.D., aged 67.

GILBERT.—On Dec. 23rd, at his residence, Brooke, Norfolk, George Gilbert, M.R.C.S., L.S.A., aged 76.

GOOD.—On Feb. 22nd, at 13, Rothery-place, Edinburgh, Fannie Russell, dearly beloved wife of J. Ernest Good, M.B., C.M.

HIGGINBOTTOM.—On Feb. 24th, at Shakspeare-street, Nottingham, Marshall Hall Higginbottom, Surgeon, aged 72.

JONES.—On Feb. 15th, at King-street, Regent-street, John Jones, M.R.C.S., aged 58.

LYALL.—On Feb. 25th, at Priory-parade, Cheltenham, David Lyall, M.D., F.L.S., Deputy-Inspector-General of Hospitals and Fleets, aged 77.

MACNAMARA.—On Feb. 26th, at Cambridge-street, Hyde-park, John MacNamara, K.S.S., M.D., aged 75 years.

MAUNSELL.—On Feb. 21st, at his residence, Cromwell-road, South Kensington, Henry Widenham Maunsell, M.A., M.D., aged 48.

PHIPPS.—On Feb. 24th, at his residence, Oxford-street, Manchester, George Constantine Phipps, M.D., F.R.C.S. Edin., in his 61st year.

SUTTON.—On Feb. 25th, at The Hollies, Holmes-Chapel, Cheshire, from pneumonia, Charles Frederick Sutton, L.R.C.P., M.B. C.S., aged 23 years, only son of Charles Frederick Sutton, Surgeon. No cards.

TOWNE.—On Feb. 23rd, at his residence, Clissold-road, Stoke Newington, N., Alexander Towne, M.R.C.S. Eng., L.S.A., in his 92nd year.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.). At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq., W.C.).—8 P.M. Mr. E. Lloyd-Williams: Some Experiments with Plastic Filling Materials. Casual Communications.—Mr. Harry Rose: On Taking Impressions of the Mouth.—Mr. J. F. Colyer: Some cases of Open Bite.

TUESDAY.—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Bertram Hunt: On the Pathology of Diphtheria.—Dr. John A. Hayward: Cultivation of Diphtheria Bacilli in Antitoxin Serum and in Hydrocele Fluid.—Dr. C. P. White: Growth of Diphtheria Bacilli in Hydrocele Fluid. Specimens illustrating the Bacteriology of Diphtheria will be shown.

WEDNESDAY.—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Inaugural Address by Dr. Champneys. Dr. J. Inglis Parsons: The Disintegration of Organic Tissue by High Tension Discharges.—Dr. Leonard Remfry: List of Ovariectomies in Women over Eighty; a Case aged Eighty-three complicated by Epithelioma of the Vulva.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Handford: A case of Cerebral Tumour following Injury.—Dr. Karl Grube: Cases illustrating the Association of Psoriasis with Diabetes.—Mr. Arbuthnot Lane: Rupture of the Gall-bladder and Liver produced by Violent Straining in a Patient suffering from Obstructive Jaundice.—Mr. Walter Spencer: Traumatic Cystic Lympho-sarcoma of the Shoulder removed after Five Years' Growth by Amputation of the Right Upper Extremity, the Flap being taken entirely from the Upper Half of the Arm.—Dr. Wallis Ord: A case of Complete Unilateral Arrest of Development with Arcus Senilis and without Hemiplegia in a Girl aged twelve years.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. W. Lang: Corneal Affections.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Aural Polypi.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Alcoholic Insanity.

ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals (VIII).

ROYAL BRITISH NURSES' ASSOCIATION.—8 P.M. Dr. W. S. Colman: Bedsores, Bladder Troubles.

SOCIETY OF ARTS.—8 P.M. Sir Charles M. Kennedy: Colonies and Treaties.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Lichen Planus and Scrofulosus.

WEST LONDON HOSPITAL (Hammersmith, W.).—5 P.M. Mr. Dunn: Eye Cases. (Post-graduate Course.)

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Q. Silcock: Glaucoma.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Treatment of Eczema.

SOCIETY OF ARTS.—8 P.M. Mr. C. W. Radcliffe Cooke: Cider.

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Mr. S. H. Gardiner: Three Periods of Seventeenth Century History—I. The Stuart Monarchy.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Dr. Arthur Voelcker: Infant Feeding.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Dr. Gowers: Clinical Lecture.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. C. Theodore Williams: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Actinomycosis and Glanders.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 P.M. Mr. F. Bowreman Jessett: Cancer of the Breast.

ROYAL INSTITUTION.—9 P.M. Prof. A. W. Rucker: The Physical Work of von Helmholtz.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Percy Smith: Climacteric and Senile Insanity.

ROYAL INSTITUTION.—3 P.M. Lord Rayleigh: Waves and Vibrations (II.).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Erythema.

METEOROLOGICAL READINGS.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

MUST THE RETIRED MEDICAL MAN SERVE UPON A JURY?

To the Editors of THE LANCET.

SIRS,—I have just retired from general medical practice, and do only consultations occasionally. Am I still exempt from being called to serve upon a jury or to hold the office of overseer? Your opinion will oblige,

Yours faithfully,

Feb. 25th, 1895.

MEDICO.

* Our correspondent still enjoys, we believe, the right of exemption. The 35th Section of the Medical Act exempts every person who is registered under the Act, who shall so desire, from serving on juries and inquests, and all corporate, parochial, hundred, and township offices, and from serving in the militia.—ED. L.

J. B. Lofthouse.—We never recommend individual practitioners; our correspondent's regular medical attendant is the person to give him the advice he seeks.

Inquirer.—Our correspondent would do well to decline to give such a certificate.

THE MEDICO-BOTANICO SOCIETY.

To the Editors of THE LANCET.

SIRS,—Can any of your readers let me know where to refer for information about the Medico-Botanico Society of 1830, run by a certain Mr. John Frost, whose doings are alluded to in the Memoir of the Rev. R. H. Barham at the beginning of the third volume of the 1847 edition of the "Ingoldsby Legends" (chap. vi.)?

I am, Sirs, yours truly,

Feb. 21st, 1895.

QUESTOR.

A CENTURY'S "BUTCHER'S BILL" IN WAR.

A highly interesting study of what a hundred years of war have cost France in human life has just been made public by Dr. Lagneau, Member of the Academy of Medicine of Paris. When the Revolution broke out France's effective army was only 120,000 men. For the wars waged during ten years in Belgium, on the Sambre, the Meuse, the Rhine, the Alps, the Pyrenees, in the Vendée, and in Egypt there were called out 2,800,000. At the census made in the ninth year of the Republic there remained of these only 677,598. In killed and in dead by disease the wars of the First Republic cost France 2,122,402 men. From 1801 to Waterloo 3,157,398 men scarcely sufficed to fill the blanks which in an incessant war against combined Europe France incurred at Austerlitz, Jena, Auerstadt, Friedland, Saragossa, Tengen, Eckmühl, Sactie, Essling, Wagram, Taragona, Smolensk, Schwarbine, Moscow, Lützen, Bautzen, Dresden, Lepsic, and Waterloo. Under the Restoration, Louis Philippe, and the Second Republic, in spite of the war in Spain (1823), the conquest of Algiers (1830), and the taking of Antwerp, France passed through a period of comparative calm. The army numbered about 213,748, and the mortality averaged 22 per 1000. In 1853-5 recommenced the epoch of the great wars—the Crimea, Italy (1859-60), China (1860-1), Mexico (1862-6), and the disasters of 1870. In the Crimea, out of 300,268 men 95,615 succumbed; in Italy, out of 500,000 there died 13,673; in China 950 and in Cochin China 48 per 1000. The Second Empire cost France the lives of about 1,600,000 soldiers. According to Dr. Lagneau's demographic tables, the century from 1795 to 1895 witnessed the death in battle or by disease of 6,000,000 French soldiers.

Sitius.—It cannot be well that young men should attempt to obtain such information from books. Moreover, the treatises written in non-scientific language are without exception misleading and generally gross and mischievous. The usual questions which arise on this topic can be answered, and constantly are answered, by the family medical man, to whom we advise our correspondent to apply.

E.R.C.S. Edin. writes: Will you please allow me to ask through your columns what books it is best to read on the subjects required for the Fellowship of the Royal College of Surgeons of Edinburgh?

Mr. J. J. Brown.—We do not see that our correspondent's communication is particularly medical in character.

"SULPHUR v. ANTITOXIN IN THE TREATMENT OF DIPHTHERIA."

To the Editors of THE LANCET.

SIRS.—Since your correspondent, Mr. Hawkins Cuthbert, has mentioned my name in his letter, which you print in your current number, will you permit me to offer a few words of comment on his contribution. No one who has had any experience of diphtheria can doubt that the remedies in which both Dr. Brownlow Martin and Mr. Hawkins Cuthbert are so much interested have any other than a good effect as local germicides. But the former is not to be blamed because he gives iron and chlorate of potash in combination with the sulphite of magnesium internally and insufflation of the same remedy locally; nor need there be any imputation on the efficacy of antitoxin because Dr. Hamilton simultaneously used sulphur locally in a case of his own. Mr. Hawkins Cuthbert says: "As long as the profession will persist in treating cases at one and the same time with two or more remedies, it is impossible to say how far each individual remedy is responsible for the result obtained." I venture to think this is comparatively unimportant so long as a patient's life is saved, for with a disease such as diphtheria, of local origin but with rapid systemic infection, it appears imperative on us to combine the best local with the best general measures in its treatment. I trust the day is far distant when in this or in any other disease a remedy will be applied to the human subject as if he were a rabbit or a guinea-pig, with the main object of obtaining mathematical results. The wonderful success achieved by antitoxin treatment at the North-Western Hospital, where that remedy—used as an auxiliary and not as a substitute for other measures—has given a mortality of under 5 per cent. (THE LANCET, Feb. 2nd, p. 305), is an object lesson of which all should take heed.

I am, Sirs, yours faithfully.

Mansfield-street, W., Feb. 23rd, 1895.

LENNOX BROWNE.

Lieutenant-Colonel.—The committee will do well to settle this question in friendly conference with A and B. They only can say when a case is sufficiently beyond the line of common practice and experience to require the opinion of a specialist. The limits of specialism are always varying.

Enquiry.—The advertisement of the lecture is not in good taste. Some licence is allowed to those who give lessons to intending missionaries, but it may easily be abused. It is more difficult to define the offence of covering in regard to midwifery than to the other branches of practice.

A *Sufferer* will probably find the information he requires in chap. iii., Part II., of Dr. Burney Yeo's work on "Food in Health and Disease," published by Messrs. Cassell and Co.

SOME POINTS IN DEATH CERTIFICATION.

To the Editors of THE LANCET.

SIRS.—I am anxious to have your direction in the following matter. Again and again when I have been called to cases where I found the patient dead on my arrival I have refused a certificate of death, and I have written to the coroner to notify him of the fact. Almost invariably that is the end of the incident. I get no acknowledgment of my communication. I have no idea as to whether the body has been buried or not, and although in many cases the information would be most interesting to me, I never hear what cause, if any, has been assigned for the death. My queries are:—1. Is this the usual practice of coroners? 2. Am I obliged by law to communicate with the coroner or his officer in cases where I refuse a certificate of death? 3. In cases where I am not satisfied with the surrounding circumstances and where the coroner, as usual, declines to hold an inquest, is there a superior authority to whom I can appeal? I may mention that the coroner for my district is not a medical man. I am, Sirs, yours truly,

Feb. 20th, 1895.

INQUISITIVE.

* 1. No.—2. No.—3. If the case is sufficiently grave, it is open for our correspondent to make application to the Lord Chief Justice of England to order an inquest.—*Ed. L.*

G. J. C. asks: Will any brother practitioner give his opinion of the probable result to be obtained by forcible manipulation under an anæsthetic of the limbs of a sufferer from chronic rheumatoid arthritis whose legs have become semiflexed at the knees?

Bayham.—The question is too large a one to be answered in the way our correspondent invites. The general principles of cardiac pathology and the peculiarities of each case must be taken into account.

Perplexed is advised to apply to her medical attendant for directions as to dissection.

"A QUESTION OF DOOR-PLATES."

To the Editors of THE LANCET.

SIRS.—In reply to a question in reference to the use of unregistrable degrees alone on the door-plates of medical men you hardly cover the point of interest, which is: Is a medical man entitled to place "M.D." on his door-plate when such degree is a foreign and unregistrable one, and under cover of this impose himself on the public as an M.D. presumably of the United Kingdom by omission of any distinguishing affix, and thus offer himself to the public as being on a par with other and registrable degrees of "Doctor of Medicine"? On this, Sirs, we ask for a definite reply as to its legality. On its honesty and honour we do not ask your opinion; but should you decide against the adverse impression many of us have formed as to the legality, I would ask you—Why open your columns to or invite comment from those who are desirous of easily attaching a coveted M.D. to their names by the addition of a new degree-granting body to the metropolis when the distinction (?) can be obtained for a few pounds?

I am, Sirs, yours faithfully,

H.

Feb. 25th, 1895.

Esculapius asks for information respecting any town or village within twenty-five miles of London, near a Great Northern or Midland railway station, having a sandy soil, pine woods, &c., suitable for an elderly patient with bronchitis.

Mr. L. A. Freeth.—To our correspondent's first question we regret we are unable to give any reply. Common lodging-houses and seamen's lodging-houses in the city of London are under the control of the Commissioners of Sewers.

Cliftonville.—We do not answer the kind of query our correspondent puts to us.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—Kent Coast Times, Sussex Daily News, Birmingham Gazette, Bradford Daily Argus, Scotsman, North Middlesex Chronicle, Truth, Manchester Courier, Brighton Argus, Leicester Post, Swansea Journal, Rugby Advertiser, North Star, Newcastle Chronicle, Liverpool Courier, Modern Society (London), Kidderminster Sun, Warwick Times, Wishaw Herald, Bristol Times, Glasgow Ballie, Heywood News, Southampton Echo, Cornish Telegraph, Shrewsbury Chronicle, Irish News, Daily Chronicle, Bedfordshire Mercury, City Press, Reading Mercury, Morning, Surrey Advertiser, Kighley News, Leeds Mercury, Citizen, Hertfordshire Mercury, South Middlesex Standard, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Courrier de la Presse, Guy's Hospital Gazette, Alfreton and Belper Journal, Australasian Medical Gazette, Local Government Journal, Northampton Mercury, Referee, Carpenter and Builder, Cincinnati Tribune, Sun, Architect, Cork Constitution, Nursing Record, Builder, Pioneer Mail, Banbury Advertiser, Times of India, Coventry Times, Isle of Ely Advertiser, Rochdale Observer, Weekly Herald and North Middlesex Advertiser, Eagle and County Cork Advertiser, Carlisle Journal, Western Daily Mercury, Answers, &c., &c.

Communications, Letters &c. have been received from—

A.—**Surg.-Major S. T. Avelton**, Baluchistan, India; **Mr. G. W. Adams**, Lond.; **Mr. A. Aitkens**, Stowmarket; **Apothecaries' Hall**, Lond., Sec. of; **A.S.V.G.**, Lond.; **Asterion**, Buckley.

B.—**Dr. G. F. Blandford**, Lond.; **Dr. A. H. Bampton**, Ilkley; **Dr. J. C. Bowie**, Clousta, Shetland; **Mr. L. A. Bidwell**, Lond.; **Mr. W. Brown**, Newcastle-on-Tyne; **Mr. T. H. The Milroy Lectures

ON

THE NATURAL HISTORY AND AFFINITIES
OF RHEUMATIC FEVER: A STUDY IN
EPIDEMIOLOGY.¹Delivered at the Royal College of Physicians of London on
March 5th, 7th, 12th, and 14th, 1895,

By ARTHUR NEWSHOLME, M.D. LOND.,

MEDICAL OFFICER OF HEALTH OF BRIGHTON.

LECTURE I.

Delivered on March 5th.

MR. PRESIDENT AND GENTLEMEN.—My first duty is to express my thanks for the honour conferred upon me by the Royal College of Physicians in electing me Milroy Lecturer for 1895. The subject selected by me for these lectures has rendered the honour one involving arduous and protracted research; and the conclusiveness of my results is necessarily limited by the imperfections of the data with which I have had to deal. If, however, in such an inquiry one were to wait until the statistical data available were perfect and complete there would be but little hope of new light; and it is, I think, the duty of the medical statistician and epidemiologist to use to the best advantage the imperfect materials in his possession, as by so doing he will at least learn how the materials may be rendered more useful for his special purposes. He will also advance the subject by paving the way for further inquiries, and may with due caution (and with full confession of the defects of his own data) hope to throw some new light on important questions of causation.

Dr. Farr early in his official life included rheumatic fever among zymotic diseases, thus formally stating his adhesion to the view that it was due to a *matcries morbi* introduced into the blood from without and leavening the whole circulating fluid. On Dr. Farr's death the Registrar-General relegated rheumatism to the class of constitutional diseases, where it still remains. In the second edition (dated 1885) of the Nomenclature of Diseases of the Royal College of Physicians, the joint committee, with greater caution, have placed it in the fourth order of general diseases, among "Morbi non in Classes Distributi." The influence of the nervous system on the joints has been investigated by Charcot, Ord, Buzzard, and many other observers, and appears to be foreshadowed in the old classification of rheumatism among the dolores. In view of the close association existing between Charcot's joint disease and definite lesions of the nervous system, and surmised to exist in rheumatoid arthritis, if not also in gout, it is not surprising that there are many who still hold that rheumatic fever is due to reflex nervous irritation, a view which is endorsed by Dr. Donkin in his recently published scholarly treatise on Children's Diseases. Dr. Donkin regards rheumatic fever as "in all probability essentially due to a faulty condition of the nervous system, for the most part inherited, which expresses itself in various inflammatory and other modes in ready reaction to diverse impressions upon the nervous periphery, among which 'chill' is probably to be regarded as chief." He adds: "It must be admitted that its clinical facts and conditions seem highly unfavourable, if not contradictory, to any hypothesis of germ origin."

In investigating the history of rheumatism it is plain that much mental confusion has arisen from the absence of a rigid definition of the word. The etiological elements proper to gout have been confused with those peculiar to rheumatism; and when this phase had been theoretically passed—practically we are still involved in it—there remained the common use of the word "rheumatism" for such diverse conditions as—(a) acute articular polyarthritis; (b) chronic articular rheumatism; (c) painful affections of the fibrous sheaths of muscles and nerves; (d) rheumatoid arthritis, and possibly several other morbid conditions of joints which

are not yet clearly differentiated. I propose to restrict myself strictly to rheumatic fever (acute and subacute rheumatism), at least until the affinities of the disease come to be considered; and by rheumatic fever I mean a disease in which there are pain and swelling of the joints, preferably of the larger joints, accompanied by fever, the joint affection having a migratory character, and usually yielding rapidly to treatment by salicylates, but liable to complicating inflammation of the pericardium or other visceral serous membranes.

Having given a definition which sufficiently indicates the scope of our inquiry, we are in a position to pursue that inquiry. The thesis, which will be advanced and supported by such evidence as is available, is that rheumatic fever is a specific febrile disease, caused by the introduction from without and multiplication in the system of a pathogenic micro-organism; that it is endemic in Europe and America and other parts of the world, but at varying intervals becomes excessively prevalent, in a manner which can only rightly be described as epidemic and even pandemic. Such a view of the causation of rheumatic fever does not cover the entire ground. Assuming that rheumatic fever only occurs when a special pathogenic micro-organism is introduced into the blood, its causation is by no means exhausted. It occurs chiefly or only in predisposed persons, in certain states of health, and under the influence of certain excitants—as fatigue, injury, and chill, the exact value of which in its causation will be hereafter discussed. Further, it occurs by preference at certain seasons of the year, in certain localities, or perhaps on certain soils. It has probable relationships with weather, climate, and ground water. We have to consider, on the one hand, the influences determining an individual attack of rheumatic fever; and, on the other hand, the wider influences determining the extent of its varying prevalence in different countries in successive years. A neglect of any of these factors will give but a distorted view of the true causation of the disease. Bacteriological studies, far from being the negation of traditional etiology, are but the logical outcome of it; and secondary causes, especially in such a disease as rheumatic fever, still maintain their traditional value as the indispensable concomitants of microbes. We have to consider not only the essential *causa causans* but the *causa efficiens*, consisting of the combined favouring influence of personal constitution and conditions of environment, which Colin has named "le milieu épidémique."² Mr. Justice Fry says: "There is, so far as I know, no physical or logical distinction between principal and minor causes or between cause and conditions in the case of two or more constituent parts of a cause, each of which is necessary, and none of which is by itself sufficient."³ This is particularly true of rheumatic fever, in which the intracorporeal condition or personal constitution and the extracorporeal conditions or environment loom larger in our mental vision than the actual infection. It would be difficult to conceive any natural condition of personal resistance or environment that would prevent a person inoculated with the virus of anthrax from being attacked by the disease. This disease and rheumatic fever may be regarded as typifying the terminal items in a long list of diseases, in which (x) infection, (y) personal resistance, and (z) environment play rôles of relatively greater or less importance. Suffice it for our present purpose that the real cause of rheumatic fever is the resultant of a combination of causes, which must all engage our attention. They may be classified as follows:—

I. *The active infective agent.*—Evidence derived from (a) epidemiology; (b) clinical history and analogies; and (c) bacteriology.

II. *Conditions of environment.*—Climate, geography and geology of the disease, season, weather, and ground water.

III. *Personal factors.*—Age and sex, constitution, temperament, heredity, previous disease, injury, fatigue, chill, occupation, diet, and race.

THE EPIDEMIOLOGY OF RHEUMATIC FEVER.

Various epidemics of rheumatic fever have been described by Pringle in the campaigns in Flanders and Holland in the middle of the eighteenth century, by Stoll in Vienna, 1776-79; by Mertens, 1782-83, and by others. Besnier,⁴ however, thinks that these epidemics may have been influenza in which rheumatic symptoms occurred, and it cannot be said that the descriptions of them leave no doubt as to their

¹ Dr. Newsholme's lectures were copiously illustrated with diagrams which we do not reproduce, as his figures and deductions tell the tale sufficiently.

² Article on *Épidémie*: Dictionnaire Encyclopédique.

³ Nature, Nov. 1st, 1894.

⁴ Article on *Rheumatisme*: Dictionnaire Encyclopédique des Sciences Médicales, p. 463.

nature. The tendency of modern observation has been distinctly to deny the occurrence of such epidemics. Thus Kelsch⁵ says these "accidental excesses do not evolve like true epidemics, not having their amplitude or cyclical regularity or course," though he admits that, falling true epidemics, "rheumatism shows oscillations independent of atmospheric influences." Professor Senator of Berlin⁶ notes that "in certain years the disease is so unusually prevalent in a particular country as to assume the character of an epidemic." He adds that "some of the older writers on medicine actually speak of 'epidemics of rheumatism,' though the essential feature of an epidemic disease—infective power—is wanting in rheumatism." Dr. Longstaff⁷ has noted the occurrence of four periods of excessive mortality from scarlet fever in England and Wales, which are shared more or less by "rheumatism accompanied with heart affection," erysipelas, pyæmia, puerperal fever, and five other diseases. Lange in Copenhagen, Chomel and Hirsch in Berlin, Fieldler in Dresden, and Lebert at Zürich among others have described local outbreaks which appeared to deserve the designation of "epidemic." There has, however, so far as I am aware, been no wide and thorough investigation of the epidemiology of rheumatic fever. It becomes necessary *in limine* to define the meaning we attach to the word "epidemic." Senator evidently regards "infective power" as an essential element in the definition; and this limitation has the highest authority in medical works. We propose, however, to use the term as applied to rheumatic fever simply to designate its relative prevalence. When it is prevalent above the average amount the disease is epidemic, though for convenience we shall arbitrarily only speak of an epidemic when the excess above the preceding minimum is at least 40 per cent. It must be left to this audience to decide from the evidence to be adduced whether in the more restricted sense of possessing infective power rheumatic fever is worthy to be described as an "epidemic" disease, or whether climatic or other causes account for the variations in its prevalence in different years. The difference between "epidemic" and "pandemic" is obviously simply one of degree. We naturally turn first to our national death returns to ascertain whether they show any evidence of epidemicity. The excess or deficiency from the mean death-rate from rheumatism in England and Wales for the whole period 1851-92 has been plotted out, so that the percentage excess or deficiency of the death-rate for any one year can be seen at a glance. The same method has been adopted in nearly all the subsequent diagrams, and they are all thus reduced to a common scale. The method of reading the diagram may be thus illustrated. In 1875 the curve was at 142—i.e., 42 per cent. above the mean line. The next preceding minimum was in 1873, when it was 90, or 10 per cent. below the mean line. The range between these two was therefore 52 per cent.

The mean death-rate from rheumatism in England and Wales during the whole period 1851-92 was 119 per million persons living. In the diagram it will be seen that the death-rate in 1855 was 15 per cent. higher, that in 1859 it was 18 per cent. higher, that in 1864 it was 23 per cent. higher, that in 1869 and 1870 it was 18 per cent. higher, and that in 1875 it was 52 per cent. higher than in the respective minimum years next preceding the above years—viz. in 1854, 1857, 1862, 1867, and 1873 respectively; and that in 1885, in 1887, and in 1890 there was evidence of smaller rises in the rheumatismal death-rate. We are not concerned at present with the general advancing wave of rheumatismal mortality from 1851 to 1875, nor with the question as to how far improved certification of deaths accounts for it; nor are we concerned with the receding wave from 1875 to the present time. The oscillations alone concern us. It cannot be maintained that varying accuracy of death certification would account for these, as any alteration in this respect would be gradually effected and not by fits and spurts. It may, however, be objected that the curve deals with "rheumatism" and doubtless includes several diverse diseases. This is so; but from 1881—when in the official reports "rheumatism" was subdivided into (a) rheumatic fever and rheumatism of the heart, and (b) rheumatism—until 1890 the first of these formed 73.5 per cent. of the whole number. It is evident therefore that rheumatic fever is the predominant partner, and we may reasonably assume that the oscillations shown in the diagram approximately correspond with, though they are less marked

than, the variations in the death-rate from this disease. The curve for rheumatism in London shows similar maxima to that for England and Wales in 1864, 1868, 1875, and 1884. The 1868 maximum takes the place of the 1869-70 maximum for England and Wales, and a maximum for 1884 that of 1885. The curves for provincial towns like Birmingham and Salford resemble the above. Among foreign death returns we may select Paris and Berlin for comparison. Both these agree with the English returns in showing a high maximum in 1875. The Berlin curve, which relates to rheumatic fever alone, runs nearly parallel with that for London, which includes all forms of rheumatism, the chief difference being that the zig-zags, as might have been expected from the smaller scale of the statistics, are more violent in the Berlin than in the English diagram. It would be easy to give other curves similar to the preceding, but I refrain from further pressing the evidence so far as it relates to deaths from rheumatism, even in towns where rheumatic fever can be accurately separated from other forms of rheumatism. Rheumatic fever is a disease with a very small case mortality. From a paper by Dr. Bryant on Hyperpyrexia in the Guy's Hospital Reports we quote the following evidence on this point: "Dr. Pye-Smith⁸ states that the average mortality in acute rheumatism from all causes is 3 to 3.7 per cent. Of 400 Guy's cases collected by him the mortality was 3.75 per cent. Of the 655 cases collected by the Investigation Committee⁹ in 1888, 22, or 3.3 per cent., died. Peacock¹⁰ collected 394 cases from the St. Thomas's Hospital Records, of which 6, or 1.5 per cent., were fatal. Syers¹¹ collected 500 cases, of which 15, or 3 per cent., were fatal."

The above percentages seem somewhat high, and they are not confirmed by Dr. Southey's cases in St. Bartholomew's Hospital in the years 1861-75 inclusive.¹²

Age.	Number of cases.	Number of deaths.	Deaths per cent.
Under 10 years	88	3	3.4
10-15 years	399	6	1.5
15-25 "	2051	30	1.4
25-35 "	1203	11	0.9
35-45 "	698	5	0.8
Above 45 years	469	2	0.4
Total	4908	57	1.16

It is probable that the fatality varies in different years; it is evident that it varies greatly with the age of patients attacked. There is, furthermore, evidence that the tendency to complications varies in different epidemics and at various seasons. For these, among other reasons, it is desirable to base conclusions as to the yearly prevalence of rheumatic fever on cases of the disease rather than on deaths from it. In most countries this can only be done through hospital records. The value of this mine of information for epidemiological research is not yet appreciated as it deserves. In connexion with the present inquiry I have collected for a long series of years the statistics of rheumatic fever in the chief general hospitals of Great Britain, and of some of the European and American cities. A few remarks must be made as to the method of employing these statistics. (a) The population of the towns from whose hospitals the returns were secured was usually an increasing one; and it was not certain that the available hospital beds would increase in the same proportion, though this was usually the case. In order to overcome this difficulty it was assumed that in any well-regulated hospital a case of rheumatic fever would always be admitted as soon as application was made; hence the proportion between the number of cases of rheumatic fever and the total medical admissions in each year would form a trustworthy index of the amount of rheumatic fever in the given town or district, assuming the social conditions of the population to remain fairly constant. It is easy to carp at this assumption, but I think it is perfectly justifiable; and although I shall not trouble you with these minute details I may state that its substantial accuracy in all doubtful cases has been confirmed by comparing the curve

secured by this method with the curve based on the original figures, and with a curve based on the ratio between the admissions for rheumatic fever and the population of the town. As we proceed I shall have to show curves constructed by each of these three methods in illustration of this point. (b) A more serious difficulty is to secure hospital returns in which the cases are uniformly classified throughout the whole period. Resident medical officers and registrars frequently change, and their methods of classification vary. One of the greatest difficulties has been to determine how to tabulate "subacute" rheumatism. Whenever there has been doubt experimental curves have been made, and by this means it has been possible to detect—when subacute rheumatism was absent from the return—whether it had been diverted into the column of "chronic" or "acute" rheumatism. Due weight has been given to all these factors, and it is believed that the curves on which my main conclusions are based approximately represent the truth. It must be remembered that in the present connexion we have nothing to do with the actual amount of rheumatic fever in a given hospital as compared with other hospitals. Each hospital is considered by itself, the records only being trusted in respect of the excess or deficiency of the case-rate in this hospital from the average case-rate for the same hospital over a whole series of years. The return supplied by Dr. Herringham from St. Bartholomew's Hospital, London, gives an excellent sample of the difficulties connected with classifying the returns, though I think that any competent person will confess that the truth would be equally reached, were one to take the total rheumatism curve or the curve for acute and subacute rheumatism, or that for acute rheumatism only. It will be found later that by having returns of both rheumatic fever and total rheumatism it has been possible to fill in blanks in curves of the former with a fair degree of accuracy. (c) It may be questioned whether as large a proportion of the cases of rheumatic fever occurring in the community find their way into hospitals as formerly. Dr. Warren, according to Watson, when asked what was good for rheumatic fever, said "six weeks." Now the pyrexial stage of rheumatic fever may under the salicylate treatment be brought to an end in seventy-two hours and the patient be discharged within two or three weeks. The shorter duration of treatment has probably enabled a larger proportion of patients to be nursed at home, and may explain a large share of the decline in hospital incidence of rheumatic fever in London shown by the curves. Whether this is so or not, such a gradually operating cause will not invalidate conclusions that may be drawn from the oscillations displayed by the downward curve. (d) As many of the returns go back as far as 1865, it is probable that in the early years there was some confusion with gout and rheumatoid arthritis. These errors would only serve to diminish the apparent oscillations of the curve and to affect the relative position in regard to the mean line for the whole period, and would not invalidate conclusions drawn from these oscillations.

We now proceed to discuss the hospital curves, starting first with those for London.

The curve for St. Bartholomew's Hospital shows a steadily increasing amount of rheumatic fever from 1867, when the record commences the maximum year 1874 (= 224), after which it declines to a minimum of 83 (mean = 100) in 1879. Between these two points, in 1871 there was a temporary ebb in the advancing tide (132 as compared with 160 in 1870). The marked decline in the curve from 1877 onwards, broken only in 1881 and 1885 by minor rises, may indicate that we have not reached the time for another great epidemic of rheumatic fever, or, as previously suggested, that hospitals are not used to so great an extent as formerly by rheumatic fever patients. The latter supposition would, I think, only explain a portion of the decline; the former supposition is favoured by the fact that the death-rate from rheumatism in London has never since risen so high as it was in 1875. We are bound to conclude that since 1875 in the districts from which St. Bartholomew's Hospital draws its patients there has been a much smaller amount of rheumatic fever than in the nine preceding years.

The statistics from St. Thomas's Hospital are somewhat confused owing to the fact that between 1862 and 1871, when the new hospital on the Thames embankment was opened, the establishment had to be carried on temporarily in Surrey-gardens. It is possible that under these circumstances more urgent cases, including rheumatic fever, were preferentially admitted, and this may partly account for the

very early maximum attained by the rheumatic fever curve at this hospital. The statistics for rheumatic fever separately are unfortunately wanting for the years 1869, 1870, 1871, and 1875. By constructing a curve for the same years for all forms of rheumatism we can, however, supply the missing links with a moderate degree of accuracy. Without laying stress on the early maximum in 1868-70 (for the reasons already stated), it is evident that, as at St. Bartholomew's Hospital, rheumatic fever was excessive in amount from 1866 to 1877, there being a slight lull in 1872 instead of in 1871 in St. Bartholomew's Hospital. Smaller rises above the mean line occurred in 1881 and in 1884, since which time there has been an uninterrupted drop.

The Westminster Hospital records only begin with 1870, and there is the further complication that subacute rheumatism is sometimes classed with acute and sometimes with chronic rheumatism. It is probable also that the rise in 1877 is exaggerated, as the total number of medical patients in that year was only 518 as compared with 878 in the preceding and with 836 patients in the succeeding year. Apart from this, the teaching of the curves, of which the one for total rheumatism is the most trustworthy, is obvious. It will be seen that there was an epidemic of rheumatic fever in 1870, which continued with the remission shown in the preceding curves until the end of 1875. A further rise occurred in 1884 of sufficient magnitude to be dignified by the name of an epidemic, and there was some evidence of a later increase of rheumatic fever in 1887. The rise in 1884 was greater in the experience of Westminster Hospital than of St. Thomas's Hospital, and at St. Bartholomew's Hospital it did not occur (and then only to a slight extent) until 1885. Judging by the rheumatic fever curve, this disease was more prevalent in the district served by the Westminster Hospital in 1884 by 60 per cent. than in the preceding minimal year (1882), and by 95 per cent. than in the succeeding minimal year (1886). At St. Thomas's Hospital in 1884 rheumatic fever was 40 per cent. higher than in the preceding minimal year (1883) and very much higher than in any succeeding year.

The Middlesex Hospital curve begins in 1867. It is characterised throughout by smaller amplitude than those already considered, though resembling them in essential particulars. The maximum, like that for St. Thomas's Hospital, was reached in 1868. Next year there was a fall, which is seen in a minor degree in the curves for St. Bartholomew's and St. Thomas's Hospitals. There was a second drop in 1872-3 from the peak of 1871, a third peak being reached in 1874, and a fourth in 1877. A further rise occurred in 1880 of 39 per cent. above the minimum of 1879; and in 1884 the amount of rheumatic fever was equal to that of 1820, but without a very great depression in the interval.

The University College Hospital curve begins in 1872 above the mean line. It touches it in 1873, and then rises rapidly to a maximum in 1876, two years later than in the more southern and central hospitals. At the Middlesex Hospital, which is nearest to it, there were maxima in 1874 and 1877. This later maximum in the University College (or North London) Hospital would lend itself to the hypothesis of an advancing northern wave of infection, very slow travelling, which started south of the Thames and probably (as we shall shortly see) in the East of London. The minimum of the University College Hospital curve following on the great epidemic occurred in 1879, as in all the other metropolitan hospitals where the records for this year are obtainable. The corresponding minimum in the metropolitan death-rate from rheumatism was in 1878-9. The 1884 rise is shown by the University College Hospital, as well as by the St. Thomas's, Middlesex, and Westminster Hospitals.

In the London Hospital curve the years 1867, 1869-70, are missing; but there was an excess of 90 per cent. in 1868 over 1866,¹³ while the 1874 rise was a comparatively small one. Unless some unknown details of hospital administration (as at St. Thomas's Hospital) account at least in part for this, there was an early maximum in 1868 (as also in the Middlesex and St. Thomas's Hospitals) as contrasted with the later maximum in 1874 in most other metropolitan hospitals. Stress need not be laid on this point, but it is evident that in all the metropolitan hospitals there were two chief maxima in the period 1866 to 1878—viz., in 1868 and in 1874-5—some having one and some the other. These obviously correspond with similar maximum death-rates from rheumatism in London in 1868 and in 1875. The London Hospital curve further differs

¹³ Since the above was written I learn that for several months in 1866 the only medical cases admitted to the London Hospital were cases of cholera. This would vitiate the ratio for that year.

from all the other curves in showing no general decline in the ratio of admissions for rheumatic fever. Whether this is due to social conditions or to a diminution of rheumatic fever in other parts of London which is not shared by the London Hospital, I am unable to say.

The St. George's Hospital curve has been constructed from the rheumatic fever cases without reference to any deviation from an average line or to the total number of medical cases each year (the latter not having been secured). It is interesting to find that, thus formed, the curve confirms the general accuracy of the preceding curves. There is a maximum of rheumatic fever in 1868, another in 1874-5, and another in 1884. The curve is further interesting as showing an earlier maximum in 1865, which probably represents a portion of an earlier epidemic of rheumatic fever in London indicated by a high death-rate from rheumatism in 1864-5.

Having now examined the curves for individual metropolitan hospitals (such as had available statistics), we are in a position to combine the picture without risk of losing the lessons derivable from its individual parts. It is impossible to make a continuous curve for all the preceding seven hospitals. The combined curve therefore represents the experience of a varying number of hospitals as stated at its foot. Beginning in 1865 with a smaller amount of rheumatic fever than the recent epidemic year of 1893, the curve at once begins to rise rapidly, reaching its chief maximum in 1868 (St. Thomas's is one of the three hospitals concerned in this part of the curve, and the fallacy in connexion with its records must be remembered). A remission in 1869 was followed by a second maximum in 1870. In 1871 occurred a second remission continuing to a less degree in 1872-3, a third maximum being reached sharply in 1874. Then followed an uninterrupted decline to the minimal years of 1878 and 1879. After this there occurred at shorter intervals the lower maxima of 1881, 1884, 1887, 1890, and 1893, with the intervening minima in 1883, 1886, 1889, and 1891. From 1889, when the amount of rheumatic fever was lower (as measured by hospital cases) than in any other year on the chart, there has been a somewhat steady rise. A general inspection of the chart appears to show an elevated plateau with minor undulations from 1868 to 1874, and then a sloping declivity, also with minor undulations, from 1874 to 1889. The London death-curve shows a similar, though less pronounced, direction; but there is a more marked valley between 1869 and 1875 than in the hospital curve. It may be surmised that we have since 1889 commenced the upward gradient of a second similar long wave; but whether this is so or not time alone can tell.

[Dr. Newsholme went through the records of many of the most important provincial hospitals in a similar manner, pointing out that in many cases statistical data were very imperfect. No distinction at some institutions had been made between acute and chronic cases, and the records in some extended much further back than in others. Records, however, from Bath, Bristol, Cambridge, Leicester, Birmingham, Sunderland, Newcastle, Liverpool, Manchester, Sheffield, Leeds, Bradford, and Hull, among others, afforded useful, if sometimes contradictory, information. In Scotland some of Dr. Newsholme's curves were based on a larger number of cases. From Ireland the information was meagre.]

LECTURE II.

Delivered on March 7th.

MR. PRESIDENT AND GENTLEMEN, — Having exhausted Great Britain and Ireland, we next consider the incidence of rheumatic fever in foreign countries, so far as trustworthy data are forthcoming. The returns from Scandinavian countries are exceptionally complete, as medical practitioners in these countries are required periodically to report to the authorities on the nature of the cases of illness coming under their charge. Dr. Beutzen, the Stadtphysikus for Christiania, has supplied me with the very valuable statistics for that city, and I have extracted the cases notified in the whole of Norway from the yearly volumes of the *Beretning om Tundhedsstilstanden og Medicinalforholdene i Norge*. The return from Christiania deals with 8577 cases of rheumatic fever compulsorily notified in the thirty-three years 1861-93. All cases are thus compulsorily notified by the medical attendant. The curve shows that there was a first epidemic reaching its maximum in 1864, when the amount was 70 per cent. above the preceding minimum in 1861. From the minimum of 1866 there was a second rise of 46 per cent.

to a maximum in 1870; and then occurred a rise of 83 per cent. from the minimum of 1873 to the maximum of 1875. After this came a steadier and slower rise of 90 per cent. from the minimum of 1878 to the maximum of 1885, the next minimum not being reached until 1890. The curve of admissions to the Christianian hospitals tells the same story as the total case curve, except that the maximum of the hospital cases occurred three years later in the epidemic than the maximum of total cases. The death-rate curve for the whole of Norway, based on 1580 deaths in the twenty-nine years 1863-91, is consistent with the corresponding case-rate curve, which is based on 67,909 cases of rheumatic fever in the same period. A comparison of the rheumatic fever case-rate of Norway with that of its capital brings out several important points. The maximum of the first epidemic is reached in Norway in 1866 instead of in 1864 in Christiania, of the second epidemic in 1871 instead of in 1870, of the third in 1876 instead of in 1875, and of the fourth and greatest epidemic in 1888-89 instead of in 1885. There is a further difference in the shape of the two curves. The Christiania curve is sharp and angular, each epidemic reaching its maximum more rapidly than the epidemics shown in the Norwegian curve. The curve for the whole of Norway runs more gradually and smoothly, corresponding with the scattered nature of the population from whose experience it has been constructed. Another suggestive feature of the two curves, so far as it relates to the most recent and greatest epidemic, cannot fail to attract attention. With epidemics starting in the same year (1883) the curve for Christiania falls to the mean line in 1889 and to its absolute minimum in 1890; while the curve for Norway, although declining in 1891, was still 20 per cent. above the mean line. Does this point to a gradual and slow spread by infection or merely indicate climatic or other differences between the capital and provincial parts of Norway? In Sweden it appears that rheumatic fever is only compulsorily notified among the poor, and unfortunately I have only been able to secure from Dr. Linroth, the health officer of Stockholm, returns for the ten years 1884-93, though he has kindly supplemented these by returns of the total number of cases of acute and chronic rheumatism in the Swedish hospitals since 1861. The notifications among the poor in Stockholm relate to 3116 cases of rheumatic fever in ten years, the return of cases in the communal hospitals to 2519 cases in the ten years 1884-93; while the return of total rheumatism in Swedish hospitals relates to 49,601 cases in the thirty-two years 1861-92. The maximum of 1886 in all these curves corresponds to the maximum in 1885 in Christiania; and if we may judge from the Swedish hospitals' curve for total rheumatism the epidemic reached its end sooner in Sweden than in Norway.

Dr. Carlsen of Copenhagen has supplied me with information as to Denmark. In this country medical practitioners are obliged to report every case of rheumatic fever that occurs in their practice. The curve for the whole of Denmark (not including the Farø Islands and other dependencies) relates to 104,999 cases in the twenty-four years 1870-93; that for deaths in towns to 928 cases; and those for Copenhagen to 24,654 cases and 429 deaths in the same period. The most peculiar feature about the case-rate for both Copenhagen and Denmark is the small range of variation in amount of rheumatic fever. In Copenhagen the absolute maximum in 1871 only differed by 63 per cent. from the absolute minimum in 1892; while for the whole of Denmark the absolute maximum of 1883 only differed from the absolute minimum in 1892 by 45 per cent. In Christiania the corresponding difference is 117 per cent., and in Stockholm (among the poor) 45 per cent. I am inclined to think that the real facts of the case are best displayed by a conjunction of the death and case curves. On this supposition there was a first epidemic, reaching its maximum in 1871 instead of in 1870, as in Christiania; a second, with a maximum in 1873 instead of 1875 in Christiania; and a third epidemic stretched from 1883 to 1888 as in Christiania.

Dr. Palmberg has furnished returns from Helsingfors, Finland, which deal with 3015 cases of rheumatic fever in the thirteen years 1881-1893 in the general population. The notification of rheumatic fever along with that of bronchitis, pneumonia, pleurisy, and peritonitis, as well as of the common infectious diseases, was made compulsory in Finland in 1880. The curve shows a minimum in 1884, which was an epidemic year in Norway, Sweden, and Denmark. In 1885 an epidemic began at Helsingfors which reached its maximum in 1890, 90 per cent. above the preceding minimum in 1884. The next minimum was in 1892, as in Copenhagen, that of

Christiania being reached in 1890. Before leaving the Scandinavian curves, two further points may be noted. The heights of the death-rate curves and of the case-rate curves appear in nearly every instance to be in an approximately inverse relationship to each other. Thus, although a high case-rate curve always corresponds to a high death-rate curve, the highest death-rate curves correspond to the *lowest* of the high case-rate curves, and the lowest death-rate curves to the *highest* of the high case-rate curves. There is some evidence of the same kind in London, where the death-rate from rheumatism was higher in 1874 than in 1868, though the case-rate was apparently lower. Are the intensity and virulence of the specific contagion of rheumatic fever in inverse relationship to the extent of its distribution? The general upward tendency of the Norwegian case curves will be noted, as contrasted with the fairly stationary character (allowing for epidemic variations) of the curve for Denmark, and with the downward tendency of the case curve for Copenhagen. In Swedish hospitals there appears to be a fairly steady increase. If more complete and perfect notification of cases explains the steady rise in Norway it can hardly be supposed that the same cause has not been operating in Denmark and in Sweden. We may compare with the above the general tendency to decline observable in the English curves and to ascend observable in the Scotch curves. It may be that we have here not merely accidental variations caused by the information from different sources being more or less trustworthy, but rather instances of countries involved in either the ebbing or flowing tide of this disease; for there are numerous indications that in addition to the epidemics at intervals of a few years there are larger epidemic waves which represent a wider and larger variation of the prevalence of the disease.

Leaving the Scandinavian returns we have next to consider others which are less complete, though they furnish valuable indications. For a valuable return from the Naval and Military Hospital of Cronstadt at the head of the Gulf of Finland in Russia, I am indebted to Dr. F. Clemow, to whom Dr. Akinkief, the senior physician of the hospital, has furnished the statistics. The curve shows the actual number of cases of rheumatic fever admitted into the hospital each year—altogether 3853 cases in twenty-nine years. The population of Cronstadt in 1893 was reckoned at 44,000, and it does not appear to have increased during the period embraced in the curve. Civil as well as military patients are admitted to this hospital. Three great epidemics are manifest—viz., in 1866–69, in 1887–88, and in 1893. Through the kindness of M. Bertillon I have received returns from Paris, relating to 3938 deaths from “rhumatismes” in Paris in the twenty-two years 1872–93, and 60,281 cases in all the Paris hospitals in the fourteen years 1879 and 1881–93. The main features of the curves based on these returns are the epidemic of 1874–75–76, which, judging by the deaths, had a maximum of 82 per cent. above the preceding minimum. Then followed an epidemic in 1880–81–82, the maximum of which was 38 per cent. above the preceding minimum in 1878 and 61 per cent. above the next minimum in 1888. The hospital cases also show evidence of the 1881–82 epidemic. The Brussels return relates to 488 deaths in the thirty-one years 1862–92. Up to the end of 1874 “rhumatisme aigu” is alone tabulated, after that “rhumatismes.” Allowing for this discrepancy, there is evidence of an epidemic lasting from 1865–72, the maximum being in 1866, and a remission occurring in 1870. After two years’ interval came the epidemic of 1875–76–77, a year later than the corresponding epidemic in Paris. A third epidemic had its maximum in 1882, and a fourth in 1888. In Berlin, during the twenty-four years 1869–92, 967 deaths from rheumatic fever were recorded. In 1879 were commenced the most valuable series of weekly returns, in which, *inter alia*, the weekly admissions for rheumatic fever into nine large general hospitals in Berlin are given. From these the hospital case-rate (in terms of total population of Berlin), based on 15,715 cases in fifteen years, has been calculated. The death-rate curve shows that 1879 was an epidemic year; that a second epidemic started in 1873, lasting, with the exception of 1876, until 1878. The death returns indicate small increases of rheumatic fever in 1884–86 and 1889; and the case returns show excessive prevalence of the disease in 1886–89 inclusive and 1884–89. For Munich I have received from Professor Dr. Ziemssen a statement of the cases of rheumatism in the Stadt Krankenhaus since 1867, which enables me to give curves of 8894 cases of rheumatism in the twenty-eight years 1867–94, stated in proportion to total medical

cases and to the population of Munich. From Dr. Aub I have obtained a statement of the yearly number of cases of rheumatism in Munich and in the whole of Bavaria for five years. These are supplied by voluntary notification on the part of medical practitioners, carried out under the auspices of a medical society. The hospital curves show that the proportion of rheumatism to total medical admissions has increased. There was a slight excess of rheumatism in 1875–76 as compared with the previous minimum in 1872, but no marked epidemic until 1878–81. After a minimum in 1882 a third epidemic reached its maximum in 1887. This, after a fourth minimum in 1892, was succeeded by an epidemic in 1893, which had not completely subsided in 1894. The curve for all cases in Munich in the five years 1889–93 (7080 in number) confirms this general conclusion, as does also the curve for total cases in Bavaria. The Prague returns supplied by Dr. H. Fabor relate to 4163 cases of rheumatic fever in its public hospitals in the ten years 1884–93. An excess is seen in 1884–85 and again in 1889–90. The returns from Vienna deal with 12,061 cases of rheumatic fever in the Kaiserlich-Königlichen Allgemeinen Krankenhaus, one of the three largest hospitals in Vienna, during the twenty-three years 1869–91, and with 30,493 cases of total rheumatism during the forty-five years 1847–91 in the same institution. The official return deals with 34,268 cases of acute and subacute rheumatism in the three chief hospitals of Vienna in the twenty-nine years 1865–93. From the first of these three curves it is not difficult to state the epidemic years for rheumatic fever in Vienna. First, there was an epidemic in 1850–51; next in 1855–56–57 (cf. a similar excess of rheumatism deaths in England in 1855–56); in 1859 a third epidemic occurred, as also in England; in 1868–69 a fourth epidemic, also seen in the English curves; and similarly in 1874–75–76, in 1882, and in 1887–88–89. The curve for rheumatic fever in the same hospital is, so far as it goes, completely confirmatory of the above; so, also, is the rheumatic curve for the three chief hospitals, except that it appears to show a steady increase from 1882–85, instead of two separate years of excess, 1882 and 1885.

The available returns from hospitals in the American continent may be next briefly passed in review. From Montreal I have returns from the General Hospital, to which English Canadian patients, and the Hôtel Dieu of St. Joseph, to which French Canadian patients are chiefly admitted. The curves show an epidemic lasting from 1870–76, but the remission occurring in 1874 in the experience of the Hôtel Dieu was the maximum in the experience of the General Hospital. In 1878 there was a great increase at the General Hospital which was almost entirely absent at the Hôtel Dieu. The next maximum is in 1883 at the Hôtel Dieu and in 1884 at the General Hospital. The fact that 1883 was a year of minimal rheumatic fever will be noted. From the Pennsylvania Hospital, Philadelphia, is a record of 2572 cases of total rheumatism in the twenty-nine years 1865–93, and of 1220 cases of rheumatic fever in the eighteen years 1876–93. The curve for total rheumatism shows maxima in 1870, in 1875–76–77, in 1884–87, and in 1890. The Bellevue Hospital, New York, furnishes 3370 cases of acute and subacute rheumatism and 6208 of total rheumatism in the seventeen years 1877–93. After a high point in 1877 come five exceptionally low years, the minimum being in 1880 as in Philadelphia. A rise occurred in 1883, which was maintained, with an intermission in 1886, until 1889. The rise in 1893 was almost unshared by Philadelphia. The Massachusetts General Hospital, Boston, had 1780 cases of total rheumatism in the twenty-four years 1870–93. The first maximum was reached in 1871 instead of in 1870 as in Philadelphia. After a remission in 1874 as in Philadelphia the rise was maintained until 1876, and was quickly followed by a second rise in 1879–80–81, only shown in 1879 in Philadelphia. The 1887 rise in Philadelphia occurred in 1888 in Boston.

I have now exhausted the available materials as to the epidemiology of rheumatic fever. In completing our survey of the field it is a pleasant duty to express my deep obligation to numerous physicians, hygienists, and resident medical officers of hospitals both in this country and abroad who have undertaken oftentimes most laborious work in securing for me the returns which I have now submitted to your attention. It is obviously impossible at the present time to enumerate those who have helped, but my sense of indebtedness is by no means diminished by the fact that the materials in many cases are necessarily fragmentary and imperfect. Before the natural history of rheumatic fever can be written in full a complete and accurate notification and tabulation of cases for

a long series of years on the system already adopted in Norway, Denmark, and Finland will be necessary. With our present imperfect information my attempt to describe the natural history of rheumatic fever is not unlike that of the palæontologist who from a few fragments of bones attempts to build up the skeleton of an ichthyosaurus. The data already given, however, enable us safely to reach certain general conclusions. 1. All the hospital records, all the Scandinavian Imperial returns of cases, and all the death returns agree in manifesting very great irregularities in the yearly incidence of rheumatic fever, the excesses of prevalence in certain years being so great as to merit the name of "epidemic." 2. A general survey of the curves indicates that there are two kinds of epidemics, which may be designated "explosive" in one case and "protracted" in the other. The explosive epidemics terminate in one or at the most three years. The protracted epidemics are seen chiefly in large centres of population or when we are studying the statistics of an entire country. It is not unlikely that these represent in reality the fusion of two or more of the explosive epidemics, which do not exactly coincide with each other in point of time. 3. There are certain favourite years for epidemics. Thus in England these are 1855-56, 1859, 1864-65, 1868-71, 1874-76, 1884-85, 1888, and 1893. In other countries the same years are frequently characterised by epidemics, but it will have been noted that in some instances there is an anticipation of or lagging behind the favourite years for England. 4. While there is no regular periodicity in the epidemic years, epidemics are apt to recur at intervals of three, four, or six years. At the same time it will have been noticed that there is in many instances a regular alternation between the explosive and the protracted epidemics, two of the shorter and smaller epidemics commonly occurring before the return of an epidemic of the protracted variety. This rule is not universal, so far as can be judged from the available data.

The great variations seen to exist in the yearly prevalence of rheumatic fever will be differently explained according as it is assumed that rheumatic fever is a constitutional disease or a specific febrile disease. If the former, variations of climate and weather, or possible variations in the susceptibility of entire populations to the disease, will be invoked in explanation. If the latter, while variations of climate or weather, or even of individual or collective susceptibility, may be admitted as secondary favouring factors, the chief explanation will be based on the presence of a greater or less amount of the specific *materies morbi*. Supporters of the former view would doubtless quote bronchitis, which causes a very variable annual mortality according to the character of the year's weather. This involves the possibly fallacious assumption that bronchitis is not a specific febrile disease, however much it may be affected by weather influences. It will be well, however, before considering the evidence of analogy, therapeutics, and bacteriology in favour of the view that rheumatic fever is a specific febrile disease, to consider the influence of climate, weather, season, and ground water on the disease.

CLIMATE AND GEOGRAPHY.

Climate may greatly affect the prevalence of rheumatic fever without affecting the question as to whether it possesses infective power. Yellow fever, although a specific febrile disease, is perhaps more directly controlled by climate than any other disease, as it can only prevail during hot and moist seasons, and is arrested by a heavy rainfall, or cold winds, or frost or snow. Rheumatic fever is probably a ubiquitous disease. So much can be said. But when we come to measure its relative amount in different countries or in different districts of the same country we are at once beset with difficulties. Deaths from rheumatic fever, even when separately tabulated, do not enable us in the present imperfect condition of death certification to form definite conclusions even in this country; and in other countries even less so. It is only in those countries in which cases of rheumatic fever are compulsorily notified by the medical men in attendance that we can obtain a fairly accurate knowledge of the total amount of this disease. In Norway in the twenty-nine years 1863-91 the annual sickness-rate from rheumatic fever was 1270 per 1,000,000 persons living, the maximum being 1866 per 1,000,000 in 1888 and the minimum 579 per 1,000,000 in 1863. The completeness of notification has doubtless improved with the lapse of time. In Denmark, where also there is universal notification, in the twenty-four years 1870-93 the sickness-rate was 2183 per 1,000,000 persons, varying from a minimum of 1600 per 1,000,000 in 1892 to a maximum

of 2800 in 1883. It will be observed that the minimum of Denmark is almost as high as the maximum of Norway. In Copenhagen the sickness-rate averaged in the same period 4030 per 1,000,000, varying from 2720 in 1892 to 5280 in 1871. It was also high in 1883 (5040) and in 1880 (5140). These rates show a still higher amount than in the whole of Denmark. In Christiania the average sickness-rate for the thirty-three years 1861-93 was 2590 per 1,000,000, varying from 1380 in 1866 to 4000 in 1885. In both Christiania and Copenhagen the notified sickness from rheumatic fever was in excess of that notified in the whole of Norway and Denmark respectively; but it is impossible to state definitely whether this is owing solely to more complete notification in these towns, or in part at least to a greater incidence of the disease on urban communities, of which there are a few indications in England. In Helsingfors there has been compulsory notification of rheumatic fever since 1880, and in the thirteen years 1881-93 the sickness-rate was 4500 per 1,000,000, varying from 2300 in 1884 to 6700 in 1890, an even higher sickness-rate than in Denmark.

Death returns for recent years, though not so trustworthy as sickness returns, may afford some indication of relative prevalence. In Berlin from 1869-92 the deaths from rheumatic fever are separately stated. They give an average death-rate of 35.2 per 1,000,000 persons living, varying from 25 per 1,000,000 in 1876 to 55 per 1,000,000 in 1869. In Vienna they are similarly separated in the years 1867-93, and the death-rate for the whole period averages 27.4, ranging from 8.56 in 1867 and 9.90 in 1889 to 37.20 in 1882 and 40.60 in 1870 and 47.3 in 1877. The average rate appears to be smaller in Vienna than in Berlin. In London during the twelve years 1882-93 the death-rate from "rheumatic fever and rheumatism of the heart" was 99 per 1,000,000, varying from 80 in 1889 to 120 per 1,000,000 in 1893. This is much higher than in Vienna and Berlin, in part at least owing to the unfortunate inclusion of "rheumatism of the heart" under the same heading. This renders the comparison useless, even if we supposed that the certification of deaths was equally accurate in the three capitals. In Paris and Brussels all forms of rheumatism are now tabulated together. In Paris in the twenty-two years 1872-93 the death-rate averaged 83 per 1,000,000, varying from 72 in 1892 and 59 in 1891 to 130 in 1875 and 110 in 1880. In Brussels since 1874 the death-rate from "rheumatism" has averaged 94 per 1,000,000, varying from 154 in 1875 and 164 in 1877 to 56 in 1881 and 35 in 1885. It is useless to continue the list. From the preceding figures it would be impossible to say with certainty in which of the cities enumerated rheumatic fever is really most prevalent, the data not being sufficiently precise for this purpose. It may be interesting, however, before leaving these death returns to compare the above with the corresponding death-rates for the capitals in which cases of rheumatic fever are compulsorily notified. In Norway the death-rate from rheumatic fever averaged 29.5 per 1,000,000 in the twenty-nine years 1863-91, varying from 45.4 in 1876 and 47.0 in 1874 to 19.1 in 1868 and 13.7 in 1864 (possibly imperfect certification). In Christiania the average death-rate in 1861-93 was 54 per 1,000,000, varying from 10 in 1891 to 170 in 1874 and 180 in 1878. In Stockholm the death-rate from rheumatic fever in the ten years 1884-93 varied from 51.5 per 1,000,000 in 1886 to 4.1 in 1893. In Copenhagen in the twenty-four years 1870-93 the death-rate averaged 70.1 per 1,000,000, varying from 87.9 in 1884 and 84.6 in 1876 and 153 in 1871 to 31.7 in 1890. In the whole of Denmark the death-rate in 1870-93 averaged 64.9 per 1,000,000, varying from 30.1 in 1888 to 94.5 in 1875. One fallacy running through these statistics, if comparisons are made, must be noted. Rheumatic fever varies greatly in prevalence and in mortality at different periods. An average death-rate for a number of

years is only comparable with another average death-rate if both populations concerned have had a common experience as regards epidemics, a condition which is difficult to fulfil. Hence the extremes in the preceding statement are of greater importance than the averages.

Indications as to number of cases of rheumatic fever in England.—A rough estimate as to the average annual number of cases of rheumatic fever in London may be made from the preceding data and the notification data for Christiania. We may assume that about half the mortality from "rheumatic fever and rheumatism of the heart" is due to rheumatic fever, so as to bring the English figures into comparison with the Norwegian. Probably this is too generous an allowance, though even then the average death-rate from rheumatic fever is 50 per 1,000,000 as compared with about 37 for Christiania. In the thirty-three years 1861-93 the average rheumatic fever case-rate was 2590 per 1,000,000. Assuming that a similar case-rate held good in the twelve years 1882-93, and that the case mortality in London was identical with that of Christiania, it follows that the average annual case-rate in London was 3500 per 1,000,000, or 3·5 per 1000. This is almost certainly an under-estimate. At least 4 persons in every 1000 are on the average attacked annually by rheumatic fever. If to this we add the number of cases of cardiac disease which were rheumatic in origin, although the articular inflammation was inconspicuous, it is evident that we have to deal with the chief cause of English mortality. Taking the case-rates as they stand, it appears that among American hospitals Chicago had much more rheumatic fever in 1886-90 than the eastern hospitals showed over a longer period. At Montreal the proportion of rheumatic fever admitted into the French Canadian was larger than into the English hospital, but whether this is a true race difference or ascribable to differences of administration is doubtful. In both of the Montreal hospitals the proportion of admissions from rheumatic fever does not amount to more than half the same ratio in the States' hospitals. Among foreign hospitals it is only possible to contrast Prague and Vienna, the proportion of rheumatic fever admissions being much larger in the latter than in the former. The Irish hospitals of Wexford and Belfast show a fairly uniform proportion of admissions in the south-eastern and north-eastern parts of Ireland. It would appear from the Scotch returns that there is more rheumatic fever in Aberdeen, judged by hospital incidence, than in Kilmarnock, more in Kilmarnock than in Glasgow, more in Glasgow than in Paisley (only a few years' records for the latter), and more in Paisley than in Edinburgh (here again only a few years' records). In the London hospitals rheumatic fever forms 8·43 per cent. of the total medical admissions (1865-93), varying from 6·41 per cent. at University College Hospital (1872-90) and 6·91 per cent. at the Westminster Hospital (1870-78, 80-93) to 10·7 per cent. at the Middlesex Hospital (1867-93). In the southern districts of England the admissions from rheumatic fever vary from 7·02 per cent. in Brighton to 10·1 per cent. in Chatham; in the midlands from 3·94 per cent. from acute rheumatism only in a short period, to 10·8 per cent. in Derby and 10·4 per cent. in Leicester from acute and subacute rheumatism; in the western counties from 12·5 per cent. in Reading and 9·71 per cent. in Queen's Hospital, Birmingham, to 5·47 per cent. in Oxford and 5·82 in Cardiff; in the north-eastern counties from 2·06 per cent. at Stoke-on-Trent and 4 per cent. at Liverpool to 5·69 at Manchester and 10·7 at Stockport; in Yorkshire from 2·12 per cent. in Huddersfield and 2·15 per cent. in York to 9·19 per cent. in Leeds; and in Northumberland from 2·83 in Newcastle to 11·6 in Durham. Now, do these differences express real differences, or is the varying proportion of rheumatic fever to total medical patients due to varying systems of hospital administration? There can be no doubt that the latter cause of variation is largely in operation, and that much of the difference shown by the previous rates must be ignored. Hospitals where no medical school exists, and more particularly hospitals in smaller towns, are apt to be used largely by the surgical staff almost to the exclusion of the medical element. The percentages of all except the largest hospitals must therefore be accepted with great caution. Furthermore, it is evident that the social conditions of towns vary enormously, and consequently any statement of rheumatic fever hospital patients in terms of total population would not be a fair criterion of the amount of this disease in two such towns, for instance, as Brighton and Leeds. The ratio between rheumatic fever hospital patients and total medical patients is much more justifiable. It is probable that in a hospital admitting all

urgent cases the percentage of rheumatic fever cases to total medical cases would fairly compare the poor of one town with the poor of another, even though in the former the poor who seek admission to hospital might form only one-thousandth part of the total population, and in the latter one-hundredth.

Having admitted to the full the scope of action of accidental and extrinsic causes of variation, there still remain certain differences of incidence of rheumatic fever which cannot be thus explained. It can scarcely be due solely to differences of administration that in Edinburgh in 1889-94 rheumatic fever formed only 2·09 per cent., in Glasgow in 1870-93 only 4·35 per cent., and in Aberdeen in 1865-93 7·21 per cent., while in London in 1865-93 it was 8·43 per cent. of total medical admissions to hospitals. At Queen's Hospital, Birmingham, the case-rate (1876-93) was 9·71 per cent., which is even higher than in the metropolitan hospitals, in Reading it was 12·5 per cent., in Bristol it was only a little lower than in London, in Manchester down to 5·69 per cent. (1870-93), in Liverpool only about 4 per cent., in Sheffield 7·08 per cent. (1887-93), and in Leeds 9·19 per cent. (1880-93). I must again draw attention to the fact that, not being able to compare exactly the same years, or, even when the same years are taken, not being certain that each town had the same range of epidemic prevalence during the period, the above results are open to criticism. Hitherto our statements as to the geographical distribution of rheumatic fever are admittedly defective. The disease is ubiquitous, but it is difficult to express numerically the varying degree of its prevalence in different districts compared with each other.

The Army figures for the United Kingdom show an excess in England over Ireland, and a still greater excess over Scotland, as in the hospital returns previously considered. In the Mediterranean Gibraltar is most subject to rheumatism, Cyprus least so. The amount among the black troops in the West Indies, and still more in West Africa, is terribly high, the sickness among blacks in the West Indies exceeding that among white troops. South Africa has a high case-rate, while in Canada the amount is about equal to that in Ireland and Gibraltar. The amount in China is low, in the Straits Settlements least of all, in Egypt it is moderately high, in Madras and Bengal high, and in Bombay about equal to Egypt. In different parts of India there are striking variations in the different military districts, which would deserve much more careful study were the data for this study extant. In the Bengal district the admissions for rheumatism per 1000 of strength vary from 48·4 in Quetta, to 21·4 in Allahabad, in the Madras district from 56·3 in Rangoon to 16·1 in the southern district, and in the Bombay military district from 66·7 in Nagpur to 15·8 in Sind.

Before leaving the question of geographical distribution of rheumatic fever I may give the results of a laborious attempt to state it accurately for the counties of England and Wales. The deaths from "rheumatic fever and rheumatism of the heart" are given separately for each county by the Registrar-General for the ten years 1881-90. The mean population of the same period having been ascertained for each county, it was possible to calculate the corresponding death-rate from rheumatic fever and rheumatism of the heart. The death-rate from rheumatic fever and rheumatism of the heart at each group of ages (0-5, 5-10, 10-15, 15-20, 20-25, 25-35, &c.) in England and Wales as a whole in the same period having been separately obtained, it was possible to apply these death-rates to the population of each county at the various groups of ages, and thus ascertain the number of deaths that would have occurred in each county from rheumatic fever and rheumatism of the heart, assuming that the deaths occurred in each county at the same rate as in England and Wales as a whole. The proportion between this total and the actual deaths in each county from rheumatic fever forms a factor of correction for age-distribution. Subsequently, the death-rate for England and Wales being taken as 100, each county was stated in proportion to this. Berkshire has the lowest death-rate of all the counties; Lancashire the highest. Lincoln is very low, which does not support the view that rheumatism has taken the place of malaria in the death returns, or that there is a close etiological relationship between malaria and rheumatic fever. London is near the average (109), Cornwall is not much below the average (93), which does not support the statement that, like the Isle of Wight and Guernsey, Cornwall enjoys immunity from rheumatic fever, as stated by Hirsch

on the authority of Forbes.¹⁴ For the rest the order of the counties is very puzzling, and it is doubtful if it represents the true order of rheumatic fever prevalence. One thing is certain—there is abundant rheumatic fever in all of them. The extreme difference is between 71 and 123, England being taken as 100. Most of the eastern counties appear to be lower than the western, but some of the western counties are also below the average. The figures, I think, bear one conclusion. Rheumatic fever is an urban disease more than a rural. The counties containing the largest and most numerous towns have with one exception the highest rheumatic fever death-rate. Thus Lancashire occupies the highest position (123); the West Riding (114) is much higher than the East Riding (85). Hereford does not agree with this result, and Cumberland decidedly not. Apart from the statements already made, the results as to county incidence of rheumatic fever are not very trustworthy. It will be impossible to speak very precisely as to the relative amount of rheumatic fever in different counties until there is a general notification of all such cases. Until that time arrives it will be impossible also to solve the problems as to the possible influence of character of soil. An attempt to classify the counties according to relative porosity of their soils was inconclusive, and a more exact attempt of the same kind for the statistics of West Sussex produced contradictory results. Climate may be described as the composite result of the interaction of temperature, rainfall, and soil. Before discussing the influence of each of these chief factors it will be convenient to discuss—

THE INFLUENCE OF SEASON.

Here we are on much firmer ground, as there is abundant evidence of the seasonal incidence of rheumatic fever. The most complete information on this point is from the countries in which rheumatic fever is compulsorily notified. The monthly curve based on 8577 cases in Christiania in the thirty-three years 1861-93 shows that the minimum number of cases occur in August, after a gradual decline to this point; and that from August onwards there is a more rapid rise, the average line for the whole year being passed in November, and 26 per cent. above this line being reached in December and 55 per cent. in January, the maximum month. The difference between January and August is 104 per cent. For the whole of Norway the seasonal curve is similar, though a little retarded, the minimum not being reached until September, and the amount in December not being much above the average for the year. The cases at Stockholm (3116 in the ten years 1884-93) also show a minimum in August and a maximum in January; but the difference between the January and August curve is only 64 per cent., as against 104 per cent. in Christiania. Further, the fall from January to August is broken in March and April, and the November rise is higher than in December. The last may possibly be owing to inaccurate data. At Helsingfors (based on 3030 cases in thirteen years) the minimum is in July instead of August. The winter rise is small, the three maximum months being March, April, and May. The difference between the maximum and minimum is 60 per cent.

Adding together the experience of the fifteen years, 1879-93, in Berlin it is evident that there is much more rheumatic fever in the first than in the second half of the year. In this respect the Berlin agree with the Scandinavian curves. They differ, however, in the fact that the amount of the rheumatic fever in Berlin remains above the mean line until midsummer, while in Stockholm and Helsingfors May is the last month much above this line, and in Christiania May already shows evidence of the summer fall. The rise in November and December is not so marked in Berlin as in Stockholm and Christiania. The slight fall in the last lunar month may be ascribable to fewer admissions to hospital about Christmas time. At Munich 2589 cases of rheumatic fever admitted to the Stadt-Krankenhaus in the six years 1889-94 show that March and May were the maximum months as in Helsingfors; but the minimum was in September instead of July as in Helsingfors, or August as in Christiania and Stockholm. Two additional curves, one based on the total cases of rheumatic fever voluntarily notified in Munich (7078 in the five years 1889-93) and in Bavaria (31,028 in the four years 1890-93), are like the hospital curve, only smoother and showing a maximum in April. Edlefsen's statistics for Kiel show out of 800 cases in 1861-84 a maximum in January,

December next approaching it, also minima in August and in February. Dr. August Stoll¹⁵ gives a maximum of 12.6 per cent. in April and 12.4 per cent. in May, next coming March with 10.9 per cent., February 10.8 per cent., June 9.5 per cent., January 8.1 per cent., July 7.7 per cent., December 6.7 per cent., August 5.9 per cent., October 5.7 per cent., November 5.29 per cent., and September 4.07 per cent. The total number of cases was 491. In Philadelphia, on the basis of 673 attacks in the years 1879-90, Dr. M. J. Lewis¹⁶ states that the maximum of 16.5 per cent. was in April, falling to a minimum of 5.1 per cent. in September. In London, judging by the weekly death-returns for the eleven years 1883-93 (4482 in number), which have been arranged in four-weekly periods, the maxima were in the eleventh, twelfth, thirteenth, and first and second periods, and the minimum in the seventh period. It does not follow that this represents the true proportion of seasonal prevalence, as there is evidence that the case-mortality and the character of complications vary in different seasons. It will be well, therefore, to take such evidence as to hospital admissions as can be obtained. Dr. H. S. Gabbett¹⁷ gives the monthly admissions to the London Hospital for the nine years 1873-81, based on 2000 total cases, or 738 first attacks of rheumatic fever. These curves both show a maximum in November. They also appear to show traces of a second maximum in July. From the Middlesex Hospital reports I find that there were 801 admissions for rheumatic fever in the six years 1874-79. These show a maximum in November and December, and a minimum in July. The Westminster Hospital returns for the thirteen years 1880-92 show that of 1116 admissions for rheumatic fever the highest number occurred in the first quarter of the year. I have extracted from the case-books the returns for Guy's and St. George's Hospitals for 1874-75 and 1892-94. The former, based on 594 cases, show that the maximum 129 occurred in the tenth four-weekly period, ending Oct. 8th, and in the twelfth, ending Dec. 3rd, the eleventh and thirteenth periods coming next to this. The minimum was in the eighth period. The first and second periods had ratios of only 96 and 98 (mean = 100). It is possible that in this curve we have to deal with the complicating effect of the London epidemic of 1874-75, which may have disturbed the regular seasonal incidence. The curves for Guy's Hospital in 1892-94 show, however, the same excess of rheumatic fever in the autumn; and this is confirmed by the London Hospital returns already quoted and by the curve of death-rate. The Berlin and Munich curves of monthly cases show the modifications to which the seasonal prevalence of rheumatic fever is prone.

Three Lectures

ON

TRAUMATIC INFECTION,

Delivered at the Royal College of Surgeons of England on Feb. 25th and 27th, and March 1st, 1895,

By C. B. LOCKWOOD, F.R.C.S. ENG.,

PROFESSOR IN SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS; ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL.

LECTURE II.

Delivered Feb. 27th.

SOME INFECTIONS OF THE BLOOD; SEPTICÆMIAS.

Definitions.—*Septicæmia* and *Sarcosepsis*.—*Method of Investigation.*—*Bacillary Septicæmia* with *Sarcosepsis*.—*Cancerous Ulcers a Source of Infection.*—*Bacterial Invasion of the Heart in Septicæmia*; *Illustrative Cases*.—*The Distribution of Bacteria in Septicæmia.*—*The Varieties of Septicæmia: Streptococcus Septicæmia.*

DEFINITIONS.

GENTLEMEN,—In its strictest acceptation the term "septicæmia" should, I think, apply to conditions in which bacteria flourish in the blood without passing through the walls of the vessels into the tissues. At the same time the bacteria may be present, and even multiplying, at the original seat of

¹⁴ Hirsch's Geographical and Historical Pathology; Translations of the Sydenham Society, vol. III., p. 756, and Transactions of the Provincial Medical Association, 1836, vol. IV., p. 174.

¹⁷ THE LANCET, Oct. 20th, 1883.

inoculation. Koch's¹ mouse septicæmia is a disease of this type. In it the bacillus multiplies at the point of inoculation and invades the blood, but is not given up by the blood to the tissues. Whilst the animal is alive, and after it is dead, the bacilli are found in its blood, and also in various bloodvessels throughout the body. Hitherto it has been difficult to demonstrate the occurrence of pure septicæmia of this type in man.

SEPTICÆMIA AND SARCOSEPSIS.

There ought, theoretically, to be a converse condition to septicæmia—one in which the bacteria flourish in the tissues, but refuse to enter the blood. Malignant oedema, or, as English surgeons more often call it, diffuse spreading traumatic gangrene, seems to be such a disease. It is well known that in it the bacillus septicus spreads along the lymph paths and shuns the blood. This peculiarity is perhaps explained by the profound aversion which the bacillus has for oxygen. After death the bacillus septicus may spread into the blood, which has then presumably lost its oxygen. Thus we may have a true sepsis of the blood or septicæmia, and a true sepsis of the tissues or sarco-sepsis. Most often, however, these two are combined.

The study of the human septicæmia is surrounded by many difficulties. Everyone has seen in histological sections of organs the blood coagulated in the larger vessels, and when this work was begun I thought it might be possible to see bacteria in this coagulated blood in cases of septicæmia. However, I have been most unsuccessful in finding bacteria in the blood of these so-called natural injections, and it seems clear that as yet nothing can be hoped for from this source. This absence of bacteria from the blood of the larger arteries and veins of men and animals who have died from septicæmia is rather mysterious, but even in such a marked septicæmia as anthrax the bacilli are not at all easily seen in the blood of the larger vessels.² Perhaps streptococci ought to be excepted from this assertion. Cornil and Babes³ found streptococci in these natural injections, and I shall allude to a case of streptococcus poisoning in which cocci and diplococci were seen in the blood and also in the smaller hepatic veins. I have, however, more than once found bacilli in the blood-clot in vessels not far from septic wounds in cases of septicæmia. (*Vide* Fig. 13.) Here, however, the mycosis may have been local and not general.

It is by no means easy to demonstrate any kind of bacterial invasion of the blood in human beings. To begin with, it is not always right or expedient to obtain specimens of blood during life or to obtain them from favourable sources. I myself have always failed to see anything definite in blood obtained by puncturing the fingers of septicæmic patients. Culture experiments with blood obtained in like manner may also be fallacious, because, to mention only one objection, of the impossibility of always disinfecting the skin. There still remain, however, the tissues and organs for examination, and they afford, I hope to show, signs as unmistakable as in mouse septicæmia or anthrax.

Great difficulties have been experienced in discovering any bacteria whatever in septicæmic tissues. Experimental pathologists are quite familiar with the occurrence of bacterial emboli in the capillaries of animals after the intravenous injection of pyogenic cocci or of other bacteria. Also, since the investigations of Recklinghausen, Klebs, Hueter, and of many others, bacterial emboli have been repeatedly described and figured in the organs of men and animals who died from pyæmia,⁴ and I could adduce many examples of my own; but hitherto the occurrence of similar emboli in septicæmia hominis has hardly been recognised, although the need of objective evidence of the kind has been severely felt. Indeed, in its absence there can be no doubt whatever that many cases of septicæmia have been thought to have been toxæmias, septic intoxications, or sapræmias. The importance of being able to determine the true cause of death in septicæmia and toxæmia by the examination of the tissues hardly requires to be mentioned. Writing in 1890, Baumgarten⁵ said that,

although bacteria have been found during life by Ogston and Rosenbach in the blood of those suffering from septicæmia, nevertheless direct evidence of their presence in the internal organs was wanting. He himself made the attempt to demonstrate their presence, but failed to do so. Cohnheim,⁶ who has done so much to elucidate embolism, says nothing concerning bacterial emboli in the capillaries in septicæmia hominis. Von Eiselsberg⁷ and many others have both before and after death demonstrated bacteria in the blood in a variety of septic conditions by using culture media. This method, however, is not always possible, and is apt to be fallacious. Von Eiselsberg and the authorities whom he quotes do not seem to have seen bacteria in the bloodvessels or capillaries after death. In one of our most recent and best works upon pathology⁸ the author, speaking of septicæmia, says: "We are peculiarly ignorant of what the organisms are which grow in the blood of man as a result of putrefaction." But in pathological literature are to be found brief references to the occurrence of bacterial emboli in the capillaries of those who have died from septicæmia. Dr. Klein⁹ says that in several cases of human septicæmia he found large numbers of minute bacilli in the bloodvessels of the lymphatic glands, and he figures such a vessel distended with bacilli. Cornil and Babes¹⁰ say that Ziemacki examined a larger number of those who had died from septicæmia, and always found zooglia of micrococci in the organs. These micrococci or zooglia were always the same, and were more numerous in acute than in chronic septicæmia. The micrococci were never found in non-infectious maladies. Klebs¹¹ has also described and depicted proliferation of micrococci in the pulmonary capillaries in puerperal septicæmia, following septic thrombosis of the internal spermatic vein. Leber and Wagenmann¹² have described an invasion of the vascular system by streptococci, but their attention is chiefly devoted to a local invasion at the point of inoculation, and they say little concerning the internal organs. I propose to refer to their observations when describing emboli in the capillaries of the liver in streptococcæmia. Cornil and Babes in their work on Bacteria depict the capillaries of the lung of an infant, the minutest vessels of which were filled with bacilli which resembled those of rabbit septicæmia. These authors also describe and depict bacteria and cocci in the capillaries of the skin of a child which died from septicæmia. Doubtless other references are to be found, but enough has been said to show that little is known concerning the occurrence of capillary bacterial emboli in septicæmia hominis.

BACILLARY SEPTICÆMIA WITH SARCOSEPSIS.

I long thought the following was a case of septicæmia such as came within my definition of that disease; but after many searches bacteria were at length discovered in the pneumonic exudation. Whether these were merely cadaveria or whether they were pathogenic I do not know. So little, however, seems to be known about septic pneumonias that it is better to describe what was found rather than to assume something which may be false. I shall, however, presently describe cases of septicæmia in which there seems to have been a true infection of the blood, such as occurs in mouse septicæmia. The case I am about to describe has a melancholy interest for me, as it is the only one of its kind I have ever had.

CASE 8 (Figs. 10 and 11).—A woman aged sixty-two years had a rapidly growing and ulcerated carcinoma of the breast, with involvement of the axillary lymphatic glands. Although the tumour had only grown for four months it was of large size, and the skin over it was cancerous in an area five inches long and three broad. In the centre of this area, in the region of the nipple, the skin had ulcerated and the cancer

was fungating. After consultation with my colleagues I removed the whole of this extensive disease, together with the axillary glands. The wound was brought together with difficulty, a drainage-tube was placed in the axilla, and many pints of sublimate lotion (1 in 2000) were used for irrigating the wound and the axilla. The skin was dusted with iodoform and a dressing applied. After the operation the patient was very restless and delirious and unable to understand what was said. These symptoms began with reaction and became progressively worse. After a while the restlessness and delirium were followed by apathy and stupor, and she died on the seventh day. Her temperature was highest on the last day, when it rose to 102.4° F.; the day before it had been 101°, and it was the same the third day; but with these exceptions it remained somewhere near 99°. The wound was painful from the beginning. About forty hours after the operation a little fluid soaked through the dressings, so they were changed. There was some redness of the skin, but the incision looked well. The drainage-tube was blocked with greyish blood-clot which had a peculiar odour, but not that of putrefaction. No bacteriological examination was made at this time, because the symptoms were thought to be due to iodoform; but the general and local conditions speedily became worse. The wound emitted a fetid odour and was covered with ashen lymph without pus. Therefore, the whole wound was opened and swabbed with tincture of iodine and fomented. The fetor abated, and the wound afterwards underwent no alteration. General infection had, however, obviously supervened from an early stage. The macroscopic appearances were, as usual in septicæmia, far from characteristic, and taken alone would have left the nature of the disease in doubt. There was a large and fetid wound due to the removal eight days previously of a large ulcerated carcinoma of the breast, together with secondarily infected axillary glands. The liver, spleen, and kidneys were normal, and no abscess or thrombus could be found anywhere. Both lungs were engorged with blood.¹³ Secondary nodules of carcinoma were met with in the liver, kidneys, and lungs. Portions of these three organs were histologically examined by various methods of staining, together with blood from the heart and fluid from the wound. The microscopic examination of the tissues yielded the following results. Pathologists have always laid great stress upon the condition of the spleen in septicæmia hominis, but its tissues were normal and no bacteria were seen, although several methods of staining were employed. The same applies to the liver. In the lungs, however, numbers of the capillaries were filled with small, non-spore-bearing bacilli with rounded ends, and usually in pairs. (Fig. 10.) At first glance the

FIG. 10.

Bacillary septicæmia. Short bacilli in the capillaries of the lung.

capillaries looked as if they were filled with micrococci, but in many of the emboli separate short bacilli could be discriminated, and occasionally chains of three or four. (All of this work was done with Zeiss $\frac{1}{2}$ in. oil immersion

and No. 3 eye-piece.) The bacilli were lodged in the smallest capillaries, oftenest in those which had a diameter equal to one coloured corpuscle, but seldom in those which had a diameter equal to two. Many of the smallest capillaries of the air vesicles were filled with bacteria, but the vasa vasorum of the smaller pulmonary vessels were clearly their favourite seat. They stained rather more purple by Czenzynke's method than some other bacteria which I am about to describe. The lungs themselves were engorged with blood, and many of the air vesicles were full of exudation, with large nucleated and granular cells in its midst. (Fig. 11.) A number

FIG. 11.

Bacillary septicæmia. Exudation into air vesicles in pneumonia complicating septicæmia.

of different kinds of bacteria were growing in this exudation. The most numerous were small, almost round bacteria, which grew in dense swarms, or in pairs, or chains of three or four elements. They were the same as the bacilli in the capillaries; where they grew in swarms within the tissues of the lung their resemblance was exact. The pairs had no capsules. Here and there the bacilli lay within the exudation cells. Like those in the capillaries, they did not stain by Gram's method, but did by Czenzynke's. Along with these small bacilli were others which were long and rather slender, and not unlike tubercle bacilli. I thought, as intermediate grades were present, that they might be the mature stage of the small bacilli. In the exudation were also numbers of big, thick bacilli of variable length. These stained by both Gram's and Czenzynke's methods. The more healthy parts of the lung contained none of these bacteria, except the small kind, which filled some of their capillaries. When pyogenic cocci are introduced into the circulation of animals the vessels of the kidneys are usually the seat of bacterial emboli; in this instance of bacillary septicæmia, however, only a few of the smallest capillaries of the kidney were filled with bacilli. These were situated in the cortex, immediately beneath the capsule, and in the walls of the straight arteries and veins of the medulla. Presently other instances will be given of bacterial emboli in the vasa vasorum of the renal vessels. Doubtless some of the bacteria in the pulmonary exudation may have been cadaveric, but others closely resembled those in the capillaries, and were probably pathogenic. It is not at all easy to think that the bacteria in the capillaries did not get into them during life. I have no hesitation in believing that they were carried there by the blood stream, and that they are evidence of the septicæmia from which the woman was thought to have died. I have examined the organs of those who died from burns, fractures, cellulitis, bronchitis, pneumonia, pleurisy, and other diseases by the same methods, and have never met with similar appearances in the capillaries. Nor have I been able to find them in kidneys or lungs which were beginning to putrefy. Moreover, the presence of bacteria in the capillaries is consistent with the clinical history and with the bacteriological investigation of the wound, heart's blood, and tissues. Bacteria with the same morphological characters as those in the capillaries of the lung were found in the fluids of the

¹³ From the notes of Mr. Berry, surgical registrar in St. Bartholomew's Hospital.

wound and in the blood of the auricle. In both, however, they were mixed with other kinds of bacteria, so that a satisfactory investigation was difficult and uncertain. The sanious and fetid fluid from the axilla contained cocci, diplococci, and staphylococci, and staphylococcus pyogenes aureus was separated from it by plate cultures. It also contained quantities of small, oval, sporeless bacilli similar to those in the capillaries of the lungs and kidneys. These also grew in short chains and occasionally looked not unlike diplococci, their ends staining more than the centre. An attempt was made to identify some of the bacteria in the wound. The earlier cultures had the same odour as the fluids of the wound and grew bacteria with similar morphological characters. Mice, rabbits, and pigeons died two or three days after inoculation with cultures from the axillary fluid. Their blood contained small oval bacilli, usually in pairs. This bacillus grew rapidly at 20° C. or 35° C. upon the surface and in the depths of culture media. The growth upon the surface was smooth and white, with abrupt, irregular edges. That in the depths consisted of small delicate white dots. Gelatine was not liquefied. The agar-agar acquired a greenish opalescent tinge. No gas was produced, and odour was absent from the older cultures. Mice died about forty-eight hours after inoculation. This bacillus was also separated from the juice of the spleen and liver. Some of the foregoing characters are like those of a bacterium which Pasteur found in fowl cholera, *Gamalela* in septicæmia of birds, and Koch in rabbit septicæmia. The opalescence of agar-agar is, however, a peculiar feature. It has been observed by Babes in cultures of his proteus septicus. The wound contained other kinds of bacilli. Some were straight with rounded ends, and about the size of tubercle bacilli; others, with sharp, indistinct ends, grew in long chains; others were short and plump; whilst others were large and grew in pairs, and looked like kidneys lying with their hilum towards one another. The bacilli with sharp ends I have seen in the pus of acute septic meningitis caused by otitis media. I cannot say to what extent these various forms represent distinct species of bacilli. Malvoz, in his admirable monograph,¹⁴ claims that the colon bacillus is extremely polymorphic. In the same culture he has seen ovoid forms, almost like cocci, a small bacillus with rounded ends, and, last, a long filamentous bacillus. By adding naphthol, alcohol, bichromate of potash, or boric acid to the media in which it is growing the bacillus pyocyaneus assumes the form of bacillus, of long bacillus, of leptothrix, of spirillum, or of spirochaeta.¹⁵ From the pus of a case of septicæmia occurring after parturition Karlinski¹⁶ obtained a pleomorphic bacterium closely allied to the proteus varieties of Hauser. It assumed coccus, bacillus, or spirillum characters according to the ways in which it was grown, and was pathogenic for white mice. No details are given of any other examination of the pus, blood, or tissues of the person from whom Karlinski obtained the bacterium.

It is quite a usual circumstance to have several kinds of bacteria in the wound and for only one kind to invade the body. For instance, in the profoundly septic wound of a patient who died after internal urethrotomy I found bacilli and cocci of various kinds. But the pus of a pyæmic abscess only contained streptococci. The bacilli did not seem to have passed beyond the wound. The blood of the auricle in this case of septicæmia also contained numbers of the small oval bacilli, usually in pairs, and many large straight, round-ended bacilli. The latter were, I think, cadaveric. Nevertheless, when some of this blood was inoculated into a rabbit, it died from peritonitis, and similar bacilli were found directly after its death in the lymph.

Although so many bacterial forms were present in this case, yet the septicæmia seems to have been caused by the small oval bacillus. My reasons for thinking so are as follows: (1) a small oval bacillus was found in the capillaries of the lungs and kidneys; (2) the same bacillus was found in the blood of the heart; (3) the same bacillus was found in vast numbers in the fluid of the wound; and (4) it was highly pathogenic for animals. Babes¹⁷ concluded from his systematic work that there were several kinds of septicæmia. In one kind all the organs contained a special non-saprogenous bacterium of a highly pathogenic type; in another the

bacilli were less pathogenic and saprogenous; and, lastly, there was septicæmia produced by pus bacteria of exceptional virulence. Babes also adds that most septicæmias are caused by several associated species of bacteria. I endeavoured to find out whence the bacillus had come which had caused this septicæmia. All the usual precautions of aseptic surgery had been used in the operation. Just before the incision the skin of the breast and the ulcerated surface were finally washed with a solution of sublimate, 1 in 1000 parts of water, although it had previously been washed and soaked in the same solution; but on reflection it seemed highly improbable that this was an efficient disinfection, and, therefore, the fatal infection may have come from the ulcer.

About this time I had under my care another patient who had a cancerous ulcer of the breast. The discharges from this had the same odour as those of the previous case. Cultures inoculated from the ulcer had the same odour and killed white mice in forty-eight hours. Their blood contained small ovoid bacilli, usually in pairs. Some were not easily distinguished from diplococci. A small ovoid bacillus was separated from the cultures which killed the mice. It was the same as that grown from the wound and organs of the case of septicæmia which I have just described. The greenish opalescent tinge which the growing bacilli imparted to agar-agar was very striking.

Hitherto, so far as I can tell, no bacillus with pathogenic properties has been found in cancer juice or cancerous ulceration. Scheurlen's¹⁸ so-called "cancer bacillus" was the bacillus epidermidis,¹⁹ and had no resemblance to the small ovoid bacillus which produced an opalescent substance; nor can I find any reference to a pathogenic bacillus²⁰ in the writings of others.

From what has been said it is clear that the secretion of cancerous ulcers would repay study by a competent bacteriologist. It is not sufficiently recognised that these cancerous ulcers are such a dangerous source of infection. Quite apart from operations, they frequently give rise to sapræmia, septicæmia, or pyæmia. That precautions ought to be taken to avoid infection from cancerous ulcers during operations is obvious. It is less clear what those precautions should be. When last I had to operate upon an ulcerating scirrhus the whole surface of the ulcer was swabbed with pure carbolic acid. This succeeded, and the wound healed by first intention under a single dressing. However, recently one of my colleagues who knew of my experience and experiments had a death from septicæmia after the removal of an ulcerating carcinoma, although pure carbolic acid had been used and every other precaution taken. This case will be described next. Upon another occasion of the same kind I should begin by destroying all the ulcer with an actual cautery.

BACTERIAL INVASION OF THE HEART IN SEPTICÆMIA.

CASE 9.—Another case of septicæmia similar to the last occurred in the same ward a year and five months later. There is the closest similarity in the clinical history, morbid anatomy, and morbid histology of the two cases, and therefore I will mention it next. The patient was a woman fifty-five years of age, who came into the hospital because of a scirrhus cancer of the right breast. The tumour had grown for more than a year and had involved the axillary glands. In its centre the growth had ulcerated over an area as large as a half-crown, and some very foul discharge was secreted by the raw and fungating surface. The operator was acquainted with the history of the previous case, and therefore extra care was taken to disinfect the ulcer and the surrounding skin. The latter was, as usual, washed with soap and water, its sebaceous matter removed with ether, and then it was disinfected with a solution of biniodide of mercury, 1 part in 500 parts of water. Also carbolic gauze soaked in a solution of biniodide of mercury was kept applied to it for many hours. Just before the operation the surface of the ulcer was brushed over with pure carbolic acid, and covered with a layer of alembroth gauze fastened on with collodion. At the operation the breast, pectoral fascia, and the axillary lymphatic glands were removed. The wound, which was very large, was closed with flaps of skin, drained, and dressed in the usual way. Nothing can be said with certainty about this patient's mental state, because she

had delusions before the operation; but she became violent directly after the operation and was never afterwards rational. She remained weak, restless, and sleepless, and after some hours of delirium was semi-comatose and collapsed, and died on Oct. 10th, the sixth day after the operation. During the last forty-eight hours it is expressly said that her pulse was extremely feeble, and was only maintained by the continual administration of brandy and of other cardiac stimulants. From having been 80 in the minute the pulse rose to 130 towards the end. The respiration hardly altered, but kept from 24 to 30 per minute. Her temperature was not much raised at first. On the fifth day it reached 102.6°F .; and on the sixth and last it rose to 103° and then to 106.6° , when she died. As a rule it ranged about 100°F . Albumen was found in the urine, but blood corpuscles and bacteria were not sought for. The wound during this illness became red and inflamed, but the edges did not come apart. Blood-stained fluid escaped by the drainage-tube, but this contained no pus, nor had it the odour of putrefaction. It seemed to me to possess a peculiar faint odour. When the flaps were opened to avoid retention of discharges a large raw surface was exposed, from which blood-stained serum exuded. This exudation contained vast numbers of small ovoid bacilli. Their average length was about 1μ , and their average breadth about 0.75μ ; but some were nearly twice as long. These bacilli multiplied by fission, and were usually in pairs. Occasionally chains of four occurred. Although there were differences in the morphology of these bacteria, nevertheless I am inclined to think they all belonged to one species.

The naked-eye examination did not give much information. The axillary vein was not thrombosed, but some of the veins of the neck were full of gas. The heart was flabby and dilated, and weighed twelve ounces; it was not otherwise diseased. The lungs were oedematous and congested at their bases. The kidneys were greatly congested and studded with small hæmorrhages. The spleen weighed five ounces, and was not diseased. Histologically, the lungs had undergone very slight alteration. Their smaller vessels were distended with blood cells and many acini full of catarrhal cells; but the evidences of bacterial invasion were either absent or not clear enough to be spoken of with certainty. I think it is probable that the small, slightly oblong bacteria had lodged in some of the minuter capillaries of the smaller pulmonary vessels and bronchioles. In the kidneys the vascular engorgement was very marked, and most of the vessels were packed with blood corpuscles, and, as usual, no bacteria could be seen amongst them. A great deal more hæmorrhage was found with the microscope than was apparent to the naked eye. Some of the extravasation was recent, some was older—perhaps a week old—and beginning to undergo the usual alterations. The renal epithelium was cloudy and desquamated in places. Some of the tubules were filled with albuminous exudation. These morbid conditions were accompanied by hardly any bacterial invasion. Occasional bacterial emboli were found in the minute vessels near the capsule and in the vasa vasorum of larger vessels near the hilum. These emboli were widely scattered and most difficult to find. They were composed of small bacteria which were very slightly oblong. The same kind were found in much greater profusion in the heart. (Fig. 12.) To the eye the heart was merely flabby and dilated, and histologically its structure was not much altered. The muscular striations were quite clear. Some of the smaller vessels were dilated and full of blood, with here and there small inter-muscular hæmorrhages. But the evidences of septicæmia were unequivocal. Many capillaries and small vessels were filled with bacteria. These were small and almost round, being about 1μ long and 0.75μ wide. They grew in swarms, in pairs, and in short chains. In some places they seemed to have begun to emigrate into the inter-muscular spaces. These small oblong bacteria have the closest morphological resemblance to the bacilli in the vasa vasorum of the vessels of the last case, and I think that they belonged to the same species. It is to be regretted that no histological examination was made of the heart in that instance. The cells of the liver had undergone fatty infiltration, but no bacteria could be found in that organ. The vessels of the brain were dilated, and many of the smaller ones stuffed with blood corpuscles. The cerebral tissues had undergone no obvious alteration, and no bacterial emboli could be found. The relationship betwixt the bacteria and the morbid process was rather unexpected. The chief morbid changes were seen

in the kidneys, but nevertheless bacterial emboli were very hard to find in these organs. In the heart, where so many emboli were found, the morbid changes were quite trivial. It seems as though there might have been a relationship betwixt the hæmorrhages and the vascular engorgement of the kidneys, the latter being due to ptomaines or toxins circulating in the blood and not to the direct agency of localised bacteria. This is also the only case in which the brain was searched for bacterial invasion. Although the result was negative it is merely an isolated and imperfect observation. I should expect that bacteria would lodge in the brain in some cases

FIG. 12.

Bacillary septicæmia. Vessels of the heart filled with short bacilli.

of septicæmia, just as they do in the heart, kidneys, liver, lungs, or other organs. The histological examination throws a certain amount of light upon a point in the clinical history. Towards the end of the disease it may be remembered that the pulse beat rapidly and the heart's failure was so marked that cardiac stimulants were given for its relief. The accumulation of bacteria in the cardiac vessels may help to explain these cardiac symptoms.

BACILLI IN THE BLOOD DURING LIFE.

I have reason to think that small short bacilli, such as were found in the foregoing cases, may be seen in the blood of living patients. Mr. Maxwell has given me preparations of blood which certainly contain bacilli with similar morphological characters, and which were made under the following circumstances.

CASE 10.—A man aged twenty-three years was admitted into the medical wards of St. Bartholomew's Hospital in November, 1894, with ulcerative endocarditis and septicæmia. The endocarditis was probably an acute attack which had supervened upon an old disease. Twice before the patient had had rheumatic fever, and once before an attack of chorea. The acute endocarditis was accompanied with aphasia, paralysis of the right side, and double optic neuritis. Although the signs of septicæmia were not of the acutest kind, nevertheless they were very clear. The temperature was raised, and usually ranged betwixt 100° and 103°F . A hæmorrhagic rash appeared upon the buttock. Delirium was almost constant at night, and towards the end he became restless and unconscious. The urine contained a trace of albumen, but was not examined for bacteria. The duration of the septicæmia may have been a little over a month. When the disease was at its height Mr. Maxwell obtained blood from the finger which contained small short bacilli singly, in pairs, and in small swarms. Their size was variable, some being as big as staphylococcus aureus and others thrice the size. They all, however, belonged to the same species, and the large elements were simply those which were in the act of division. The specimen which contained such an abundance of bacteria was obtained after the skin had merely been washed with soap and water; but four days later some blood was obtained after the skin had been scrubbed with soap and water, rubbed with ether, and disinfected with a 5 per cent. carbolic lotion. The blood still contained the same bacteria;

but in much fewer numbers. Attempts to grow these bacteria upon culture media ended in failure.

Experimentalists are quite familiar with the disappearance of bacteria from the blood after massive doses have been injected. Saprophytes disappear the most quickly, and in a few hours none survive; but even pathogenic bacteria soon diminish in numbers, and may entirely vanish.²¹ Thus there is nothing surprising in the occurrence of many bacteria upon one day and their diminution upon another. Dr. Kantback, our pathologist, has of late had no difficulty in finding staphylococcus aureus and streptococcus pyogenes in the blood during life in pyæmia and ulcerative endocarditis. In cases of so-called septicæmia none were found, and these all recovered.

SEPTICÆMIA WITH BACTERIAL INVASION OF THE HEART, PERICARDIUM, AND PLEURA.

CASE 11 (Figs. 13 to 16).—One of the cases of septicæmia (Case 8) which has been described died on May 19th, 1893. It was preceded by another in the same ward which died rather less than a month before, on April 26th, 1893. The two cases resemble one another in some particulars, but differ widely in others. They will be contrasted after I have given the details of this, which was the first to occur. The patient was sixty-five years old and had been a widow for two years. In August, 1890, a small carcinoma was removed from the right breast, together with some enlarged axillary glands. This operation was followed by no recurrence *in loco*, but in April, 1893, the left breast was amputated for the same disease, and the axillary lymphatic glands, being enlarged, were removed. The day after the operation the woman was quite comfortable, without pain, and with a normal temperature. Upon the third day her temperature had risen to 102° 2' F., and on the fourth she was very ill with a temperature of 102° 3', an inflamed throat,

The examination was made twenty-five hours after death. The operation wound was said to have appeared healthy. The brain and organs were normal, with the exception of those in the thorax. The surface of the pericardium was covered with a thin layer of recent lymph, and contained about an ounce of purulent fluid. The lungs were slightly congested and the pleurae universally adherent by a thick layer of recent yellow lymph. There was very little fluid in the pleural cavities. Recent thrombi were found in the anterior jugular and in some of the neighbouring veins. As a rule, bacteria are hard to find in blood-clots, but in this instance the firmer and most fibrinous part of the clot from the anterior jugular vein contained numerous groups of short bacilli with rounded ends, and often in twos. (Fig. 13.) In some parts of the clot they grew in leptothrix of some length. This is not seen in the part of the clot which has been drawn. It is shown, however, in Fig. 16. The bacilli were in vast numbers amongst the fibrin, but in places where the blood corpuscles predominated none were seen.

The present seems to be a favourable opportunity for showing a micro-photograph which Mr. Cosens has made of a clot from the femoral vein of another woman who died from septicæmia after an operation for necrosis of the femur. The bacteria in the clot are short bacilli, the same morphologically as those which I have just described. The patient died forty-eight hours after the operation with coma and high temperature. But to return to the case under consideration, the lymph which covered the visceral layer of the pleura was in places a quarter of an inch thick. Mixed with its cells and fibrin were bacilli of more than one morphological variety. By far the most abundant were small oval bacilli 1.5 μ to 2 μ long and 0.75 μ wide, which occurred chiefly in pairs in short chains of from four to eight or ten elements (Fig. 14), and in small irregular groups. Here and

FIG. 13.

Bacillary septicæmia. Bacilli in blood-clot in the anterior jugular vein. In some parts of this clot the bacilli grew in leptothrix.

and some redness of the wound, unaccompanied with discharge or suppuration. Upon the fifth day, although she felt better, there was some fulness in the axilla, with tenderness about the shoulder. The mind was quite clear except at night, when she was slightly delirious. The urine was acid, with a specific gravity of 1022, and a cloud of albumen when heated. Upon the seventh day she died with failure of the heart's action; her pulse, which had been at the rate of 118 to 120 per minute, fell to 112 and then to 60. The respiration, too, was rapid, having risen from 27 to 42 during the course of her illness. The temperature, which had averaged 102°, fell to 99° 8' on the day she died. There was never any coma, and the mind was clear throughout.

²¹ Numerous references are given by Thomas in Neubauer and Vogel's Harnanalyse; also by Wyssokowitsch in the Zeitschrift für Hygiene, 1886.

FIG. 14.

Bacillary septicæmia. Pleuritic lymph containing a variety of bacilli.

there, especially near the free edge of the lymph, were a few short and thick round-ended bacilli in pairs. It seems probable that this was a bacillus which occurs in dead tissues, and is called by Sternberg the "bacillus cadaveris."²² I cannot speak so confidently about another bacillus which also was present in considerable numbers. It was about the size of the anthrax bacillus, but with oval ends; it grew in pairs, or in short chains with ill-marked intervals between the elements. The pleura was acutely inflamed with engorgement of its vessels and proliferation of its endothelium. Its tissues were interspersed with bacilli the same as those which have been described. Here, again, the small oval bacilli in pairs and chains were by far the most numerous. These filled many of the smallest bloodvessels and lymph spaces, but were absent from the blood which distended the larger arterioles and venules. Most of the air-vesicles beneath the pleura were filled with pneumonic

²² Manual of Bacteriology, p. 4

exudation, which contained numbers of the small oval bacilli. Bacilli were most numerous near the pleura, but both they and the exudation diminished in the vesicles further removed from the pleura. The tissues of the lungs also contained the two other kinds of bacilli seen in the pleuritic exudation. The pneumonia was the same as that in Fig. 11. No bacterial emboli were found in the capillaries of the pleura. The description of the pleural lymph applies to that which covered the pericardium. It likewise contained numbers of bacilli with similar morphological characters. Slight histological differences were also observed. For instance, the pericardial lymph was thinner and more villous and the subjacent endothelium detached in places as if by vesication. Thus the pericardial and pleural lymph probably contained three kinds of bacilli. The two largest are common in cadavers and may have been saprophytes. The small oval bacillus may also have been of the same nature, but the examination of the tissues of the heart, and, I might add, of the other organs, suggests that it played a much more important part and was the cause of the septicæmia. Many of the capillaries and smaller bloodvessels of the heart were filled with these small oval bacilli. (Fig. 15.) In many places the

condition was characterised by apathy, stupor, and coma; in the second the mind was clear throughout, with only slight delirium at night. In the first the temperature was low, averaging 99° F.; in the second the temperature was high throughout, usually 102°, and only fell as the patient was dying. In the first the chief morbid appearance was pneumonia, in the second pleuritis and pericarditis. In both, these diseases were associated with, and probably due to, a small oval bacillus; but in the first case this was almost quite confined to the vessels, and in the second it had passed from the vessels into the tissues. Indeed, the only point of close similarity between these two cases was the morphological resemblance of bacteria found in them. The circumstances that both patients were women of nearly the same age, that both had had the same disease, and that both had had the same operation done in the same ward and almost at the same time, suggested that they had both incurred the same kind of infection; however, the differences which have been pointed out do not, in my opinion, permit such a simple hypothesis.

CASE 12 (Fig. 17).—The following seems also to have been a septicæmia in which sarcosepsis was beginning.²⁴ It differed, however, in important particulars from the pre-

FIG. 15.

Bacillary septicæmia. Short bacilli in the bloodvessels of the heart.

dilated inter-muscular lymph spaces were also full of them, and where they were not crowded together the usual chains of from six to ten elements were seen. (Fig. 16.) Here and there the bacterial emboli filled minute bloodvessels beneath endothelial covering of the heart. Some of the muscle fibres also contained the bacteria in their substance, but not enough to distend their sarcolemma as in a case of pyæmic myocarditis described by Cornil and Babes.²³ The kidneys, too, had not escaped. Their epithelium was slightly cloudy, and had desquamated in some of the larger collecting tubules. Some of the smaller tubules contained albuminous casts. The bacterial invasion of the kidneys seemed to have been but slight. With much trouble it was ascertained that some of the smaller capillaries and vasa vasorum of the bloodvessels and connective tissue of the medulla contained bacterial emboli. It is to be noticed that the histological examination throws light upon two features in the clinical history. Apart from the pericarditis the bacterial invasion of the muscular substance of the heart is, I think, sufficient to account for the failure in the action of that organ, which seems to have been the immediate cause of death. Next, the bacterial emboli in the kidneys must have had a relationship to the presence of albumen in the urine. The association of pleuritis and sub-pleural pneumonia with rapid respiration hardly requires comment.

If we contrast this case of septicæmia with another (Case 8) which occurred in the same ward, the following differences in their clinical symptoms, morbid anatomy, and morbid histology are to be noted. In the first the mental

FIG. 16.

Bacillary septicæmia. Short bacilli in the inter-muscular and sub-pericardial lymph spaces of the heart.

ceding. A man aged seventy-four had had varicose veins for forty years; these were followed by ulcers, which became septic and caused cellulitis of the leg and thigh. Free incisions were made into the suppurating areas, but his general condition became serious and such as is often seen in the septicæmias, from which disease he was thought to be suffering. His mind became dull and apathetic, he was drowsy and had to be roused to take his food, and he was delirious at night. His thigh was amputated through the upper third, and the operation was well borne. He died, however, twelve hours afterwards from syncope. During his last illness his temperature was usually between 99° and 100° F. It once reached 101° soon after the cellulitis set in. His urine contained no albumen and had an acid reaction and a specific gravity of 1022.

Mr. Shuter made an examination twenty-six hours after death; the weather was cool at the time. The brain, spleen, and kidneys were normal. The liver was cirrhotic, with stones in the gall-bladder. The lungs had scars and calcareous nodules at their apices, and were congested at the base. The heart was thick, soft, and with fatty walls; the tricuspid valve was ulcerated; the mitral valves were thickened and covered with vegetations; one cusp was almost non-existent. The great vessels were atheromatous. The ulceration was recent, but the other valvular changes were of long standing. Thus there was in the heart enough to explain the fatal syncope. But most of the disease was not of recent origin, and therefore we have to

²³ Les Bactéries, third edition, vol. i., p. 540 (Fig. 211).

²⁴ I am indebted to Mr. Groves for much assistance in the investigation of this case.

try to find out what precipitated the sudden failure of the heart's action. The main histological evidence of septicæmia was in the heart. The muscular substance had in places undergone slight fatty degeneration, but looked equal to its duties. There was a good deal of fatty infiltration. The venules and intramuscular capillaries were greatly dilated. Some of the capillaries were full of blood, but the veins contained none. The heart had evidently been engorged with blood. Some of the smaller venules had clearly been plugged with bacilli. (Fig. 17.) Vast numbers of bacilli still adhered to

FIG. 17.

Bacillary septicæmia. Large bacilli in bloodvessels of the heart.

their interiors, although it looked as if the bulk of them had been dislodged when the section was cut. These bacilli had slightly rounded ends. They sometimes occurred in twos, but not in strings. They were almost 1.5μ wide, and their length was twice, thrice, or four times their width. They were as long as, but thicker than, anthrax bacilli. They had evidently multiplied by fission, but some of the larger bacilli had two or more clear spaces in their substance, which suggested the development of spores. In size and appearance these bacilli were exceedingly like the common and harmless hay bacillus (*Bacillus subtilis*). Although grouped in the interior of the venules, some of the bacilli had penetrated the walls of the vessels and entered amongst the fat and muscular fibres. In places they had clearly been dragged amongst the muscular fibres and fat by the process of section cutting; but elsewhere some of the fat was infiltrated with vast numbers. The lungs were slightly hyperæmic, with catarrhal proliferation of their epithelium. Some of the vessels contained blood-clots, but no bacilli could be seen in these, or, indeed, in any other part of the lungs. The kidneys had merely undergone senile changes; they contained no bacteria. The liver likewise contained no bacteria; it was cirrhotic, but not in an advanced degree. The spleen was soft and pulpy, but no bacteria could be found in either its bloodvessels or tissues. If I am right in inferring that the heart had been engorged with blood, we would have some kind of explanation of the localisation of the bacilli in its venules and tissues. Karl Huber²⁵ has shown by an ingenious experiment that bacilli circulating in the blood localise themselves in hyperæmic areas. He inflamed the ears of rabbits with croton oil and then inoculated the tail of the animals with anthrax. The accumulation of anthrax bacilli in the inflamed ear was very decided. Thus the engorgement of this patient's heart may have determined the localisation of bacilli in the vessels. Beyond this it would be rash to go. If we suppose that the disease of the heart constituted a *locus minoris resistantie*, at which the bacteria congregated, it must not be forgotten that no bacteria were found in the liver, which was cirrhotic and, I ought to add, congested in places. Judging from their drawing, Cornil and

Babes²⁶ seem to have met with a bacillary invasion similar to this in the case of a child twelve years old who died from a subacute septicæmia following cutaneous ulcerations. The bacilli were found in the vessels of the kidney, lungs, pleura, and in those of the skin. They were accompanied by a coccus infection, probably *Streptococcus pyogenes*.

THE DISTRIBUTION OF BACTERIA IN SEPTICÆMIA.

The unequal distribution of the bacteria is a feature of these cases of septicæmia. They seemed to have congregated in a single organ, such as the heart, lungs, or kidneys, in preference to the others. Whether this is an accidental or constant feature my cases are too few to decide; nevertheless, the possibility of its occurrence ought to be taken into consideration. Clearly the absence of bacteria from the body cannot be inferred from their absence from one or more of the organs. This congregation of bacteria in particular organs has struck other observers. Cornil and Babes²⁷ refer to it particularly under the heading of "primary bacterial nephritis." It is probable that when bacteria are circulating in the blood conditions of which we as yet know little determine their arrest in particular regions.

THE VARIETIES OF SEPTICÆMIA: STREPTOCOCCUS SEPTICÆMIA.

That septicæmia is not always a bacillary invasion of the blood, as might be inferred from the foregoing, was, I think, clearly shown by the following case of septicæmia following erysipelas.

CASE 13.—A stout woman aged fifty-five years was admitted into the isolation ward with cutaneous erysipelas of the right arm. There were the usual redness, swelling, and bullæ, with enlargement of the axillary lymphatic glands. The general symptoms were severe, with rigors, nausea, and a temperature of 104°F . The erysipelas spread from the arm to the back, shoulder, chest, and abdomen. It was still spreading on the seventh day, and upon the eighth she became restless and collapsed, with a feeble pulse. She died exhausted on the evening of the ninth day. Before the end the bases of her lungs, especially the left, became pneumonic, and her death was attributed to this complication and to septicæmia.

The examination disclosed nothing beyond what has been stated. There was much oedema of the cellular tissue of

FIG. 18.

Streptococcus septicæmia. Streptococci in the blood of the right auricle. From a micro-photograph by Mr. Cosens. The lecturer is indebted to Messrs. Cassell and Co. for this figure, which is from his forthcoming article on Erysipelas in "A System of Surgery," edited by Mr. Treves, and now in the press.

the arm, axilla, and chest, with swelling of the lymphatic glands. The left lung was congested, but not solid; the right lung was also congested. The kidneys were much congested and swollen. The serum of the inflamed cellular tissue contained cocci, singly, in pairs and short chains. These were seen in cover-glass preparations. Sections of the inflamed tissues were crowded with cells, and the cocci

²⁷ Ibid., vol. i., p. 545.

could not be seen with certainty. As the disease was of some days' standing this was not unexpected. The blood of the right auricle contained vast numbers of streptococci in short chains and entangled into masses. (Fig. 18.) Here and there the blood contained rather long, straight, or slightly curved bacilli, which were probably cadaveric. The lungs were enormously engorged with blood, and the air cells full of catarrhal exudation. Numbers of the smaller capillaries were plugged with micrococci. The emboli occurred in the capillaries of the walls of the air cells, and also in those in the walls of the pulmonary vessels and bronchi. (Fig. 19.) No chains could be discerned in these emboli, but none can be seen, as a rule, in similar emboli produced artificially by injecting streptococci into the circulation of rabbits. The

FIG. 19.

Streptococcus septicæmicæ. Micrococci in capillaries of the lungs. Two cadaveric bacilli are shown in the upper part of the figure. The blood contained others of the same kind.

kidneys were likewise engorged with blood, and the epithelium of their tubules was in an advanced state of cloudy swelling. Some of the smallest capillaries near the cortex and in the walls of the renal vessels were plugged with micrococci, as in the lungs; in the kidneys, however, the emboli were not so numerous. No bacteria were found in the liver, and the other organs were not examined. It is to be regretted that no examination was made of the heart. The clinical history seemed to show that that organ had not escaped the infection.

THE SO-CALLED ANTITOXIC TREATMENT OF INFECTIVE DISEASES, ILLUSTRATED BY DIPHTHERIA.¹

By BERTRAM HUNT, M.B. Oxon.,

ASSISTANT IN THE DIPHTHERIA DEPARTMENT AT THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

DR. BERTRAM HUNT, after acknowledging his indebtedness to his friend Dr. Ruffer for having suggested to the Pathological Society that he should open the discussion, stated that he would deal with the subject in the following order: (1) a short glance at the history; (2) the bacteriology only so far as was necessary to a proper understanding of the production and nature of the toxin; (3) the result of introducing this toxin into animals with the production and nature of antitoxin; and (4) the pathology so far as it affects the prognosis of the treatment. The history divides itself into the prescientific and the scientific ages. The latter period may be said to have commenced with Pasteur, who discovered that protection could be conferred by artificial mitigation of

virus, the honour of which discovery is fully shared by Koch. In 1887 Salmon and Smith proved that not only mitigated bacteria but their products were able to confer protection, Sewall that immunity was possible to cobra poison, and Fodor that the blood was able to destroy bacilli. In 1891 Behring showed that if immunity to tetanus or diphtheria had been conferred upon animals their blood or serum was found not only able to protect other animals against either the bacteria or their soluble specific poisons, but even to cure them if injected subsequently to the virulent matter; and as a mixture of the serum with the toxin *in vitro* was found to be quite innocuous he called the serum "antitoxic," and the unknown substance in the same "antitoxin." In 1891 was published, too, what might be regarded as the first reading-book on this subject—namely, Ehrlich's work on the immunity conferred by feeding on animals against the vegetable poisons ricin and abrin. There are, therefore, two methods known of protecting against infective disease: (1) active immunity (more or less permanent) by the Pasteur method of introducing mitigated virus, with consequent slight illness, recovery, and protection against a virulent virus; (2) passive immunity (temporary only) by the Behring method of introducing mitigated bacteria or their products, with slight illness, recovery, and protection against a virulent culture or toxin, and the transference of this immunity to another animal by the injection of blood or serum taken from the first. In the first method the animal forms its own antitoxin; in the second it is previously formed in another animal and transferred as a therapeutic agent.

Production of the toxin.—Roux and Yersin noticed that a certain supply of oxygen to the bouillon culture increased the virulence of the toxin, which depended chiefly on the alkaliescence of the medium. It being troublesome to pass air through a culture, he (Dr. Hunt) had devised methods of obtaining bouillon surface growth whereby a virulent toxin is quickly attainable by floating powdered cork or little rafts made of cork wrapped round with wool and muslin, which serve as nutrient islands. The bacilli have an inveterate predilection to spread over a surface. The question of the action of oxygen on a pathogenic bacillus is extremely important and interesting. The virulent bacillus renders its culture media acid in twenty-four to forty-eight hours; the toxin is only found in an alkaline culture—and is, as he would suggest later, only soluble in an alkali. The action of the oxygen, in his opinion, was to prevent the acidity altogether, and although its free admission tends to encourage a merely saprophytic or non-pathogenic growth of bacilli, this disadvantage is more than counterbalanced by the maintenance of an alkaline reaction. Dr. Ruffer has found that cultures exposed freely to a supply of air do remain alkaline. Pasteur's classical experiments with yeast cells form an interesting comparison, for he found that surface cultures freely exposed to the air developed a vigorous yeast; yet there was little or no fermentative action, this only taking place when some of the aerobic cultures were afterwards cultivated anaerobically. There is no evidence that this exuberant aerated growth of bacilli has acquired any accession of virulence. In fact, as he (Dr. Hunt) had shown as regards methylene blue and the diphtheria bacillus a constant supply of oxygen, allowing of permanent reduction, is soon fatal to them. A free admittance of oxygen to the culture promotes, therefore, the growth of the bacilli, and leads to an early formation of the toxin, suggesting that the specific poison is some constituent of the bacterial protoplasm. Bacterial specific poisons were at first supposed to be ptomaines, and, although bacteria do many of them produce alkaloidal and other poisons, they are of no importance to the subject under consideration that evening, nor, indeed to any problem of immunity, in that they are not specific. Brieger and Frænkel described a poisonous proteid which they called toxalbumen or proteid poison—an excellent name, as it implied a specific nature. In this country Hankin and Dr. Sidney Martin described the formation of albumose. The choice of the word albumose was unfortunate, for it was necessary to distinguish carefully between the vital chemical processes of the bacteria and of the action of these on their environment. Buchner had succeeded in growing tetanus bacilli in a solution of asparagine and in obtaining by precipitation a most virulent toxin. Experiments showed that toxin was elaborated not in the media but in the protoplasm of the bacteria—a proteid poison being formed in a solution containing no albumen, and that the production of bacterial poison was due to synthetic and not fermentative action. He would define, then, the diphtheria toxin as a specific proteid poison. But it must

¹ Abstract of a paper read before the Pathological Society on Tuesday, March 5th.

be clearly understood that it was not necessarily the proteid which was the poison, but what might perhaps be described as its disposition, its active and specific quality. Such active proteids had been called living proteids, and if this were adopted, then the toxic quality must be defined as the life in the proteid. The proteid having adherent to it this toxic quality is probably the myco-nucleo-albumen described by Gamaleia, a substance soluble only in alkaline media. This toxin, this vital chemical quality of bacterial protoplasm, was concerned in the metabolism of the bacteria, but it also constituted the offensive and defensive weapon of the microbe in its struggle for existence. He would say that in all living cells the protoplasm had this vital function. It was necessary, he thought, to regard the animal organism as a collection of pure cultures of cells of various types living together in harmony and in a state of complete chemical compatibility; as the forms of life fittest to survive in that particular environment the animal body; as resisting the intrusion of foreign substances, whether alive or dead, and with offensive and defensive weapons to maintain their existence, these weapons being chemical ones. In short, applying Darwinism to this question of immunity, we may consider the strife between the cells and the bacteria as a struggle for existence fought out between the synthetic vital processes arrayed on both sides. In animals which had a natural immunity to any infective disease it was obvious that the specific myco-proteid elaborated by the bacteria causing that disease must be either inoffensive or easily destroyed by the cells, and that it would occasion no struggle, no additional chemical activity in the animal cells—i.e., no constitutional or local disturbance. It ought not to be expected that such a body should be modified in any way, but merely excreted or quietly and quickly destroyed. In susceptible animals, on the other hand, there was a struggle, for a foreign proteid was introduced that was offensive and harmful to the animal organism, which organism, if it gained the upper hand, was able to yield us a substance of the highest therapeutic value.

Behring enunciated certain laws which must be obeyed in the process of immunisation. 1. It was absolutely necessary to wait until the animal had completely recovered before a fresh injection was given. 2. That the antitoxic value of the blood reached a maximum coincidently with this return to perfect health and then fell somewhat to a more or less constant level for a time. 3. That any fresh injection of toxin was best made when the antitoxin value was at its highest. 4. That the more susceptible the animal the greater the degree of immunity finally attainable and the more antitoxic the blood. 5. That the immunisation could be carried too far and a condition allied to natural immunity or a poison-proof state brought about. Behring chose the sheep, but their immunisation is a tedious process, and consequently Aronson and Roux chose the horse. Antitoxin was very different in its action to that of any modification of toxin as yet known to us. For it was therapeutic, whereas toxin mitigated by any of the ordinary methods if injected simultaneously with virulent toxin was found to accelerate the fatal termination. Antitoxin was, moreover, perfectly harmless, and the immunity which it conferred was immediate and temporary. Buchner had settled once for all time that direct antitoxic antidotal action of the antitoxin to the toxin neither took place *in vitro* nor in an animal organism, as had been maintained at first by Behring. The two substances—antitoxin and toxin—existed side by side, and no neutralisation occurred. Antitoxin, moreover, acted merely as a stimulus to the chemical processes of the cells, and if these cells be enfeebled in any way and their vitality lowered, the stimulus failed to rouse them and the antitoxin was of no avail. Just as in animals immune to diphtheria a curative substance was found in the blood, so presumably a similar curative substance must be obtainable in the case of all diseases caused by the invasion of the animal organism by any kind of cell foreign to it. A law, therefore, might be laid down that, whenever disease is set up by the invasion of any other form of life into the animal organism, immunity to such disease would confer curative properties on the blood of the immune animal. This curative quality of the serum in immunity to diseases had been designated as antitoxic only in tetanus and diphtheria, and not in the others, because the bacteria concerned in their production did not produce any definite specific poison for the serum to have been erroneously supposed to be able to neutralise. It had not been called

antibiotic because it was far easier to show that such serum possessed no antibiotic power than that so-called antitoxin had no antitoxic power. Hence, antitoxin has not been invented to describe such curative agents. It must not be supposed, however, that any possible increase of the natural germicidal power in the blood of the immune animal was denied, but it was only maintained that the substance here designated antitoxin had no antibiotic qualities in itself, and, as Buchner had pointed out, the serum of an animal might be deprived of its antibiotic or bactericidal quality by heat, and yet could retain its specific curative quality. In order to prove that antitoxic treatment was in reality a rapid process of immunisation it was only necessary to compare the action of these antitoxins with diphtheria antitoxin. (Reference was here made to Pfeiffer's experiments on the blood of animals immune from cholera.) The treatment of guinea-pigs with curative serum in experimental cholera injection might be defined as being merely a rapid immunisation method, so rapid as to be practically instantaneous, and there was no reason to doubt but that the action of antitoxin in diphtheria was precisely similar. The best way, therefore, to express the method and meaning of this process of protection was by calling these protective and curative qualities of the blood of immune animals specific immunising or curative agents.

Attention might now be drawn to the rapidity of the immunisation in diphtheria. In an ordinary poisoned wound of the finger the absorption of the poison could be traced along the lymphatic system. In simultaneous injection of diphtheria toxin and antitoxin the mixed solution must pass through the lymphatic glands, and in the presence of the antitoxin the cells were able to deprive the toxin of its injurious character, and, therefore, no illness resulted, and there might be no local reaction—in other words, a condition of immediate immunity would seem to be conferred on the tissues in which the injection was made. Buchner would seem at one time to have thought that antitoxin might be obtained directly from the bacterial protoplasm, but it must be considered, he (Dr Hunt) thought, to be either a direct or indirect product of the animal cells, either as a secretion or as an excretion. Buchner had given a valuable comparison between the bactericidal substance present in serum—namely, alexin, which was a direct product of the animal cells and the so-called antitoxin. Alexin was able to destroy bacilli, was very unstable, and varied with the species. Antitoxin, on the other hand, had no bactericidal action, could withstand a temperature of 70° to 80° C., was unaffected by sunlight or putrefaction, and never varied with the species of animal, but always with the species of bacteria through whose agency it was formed. Tetanus antitoxin cured tetanus, but not diphtheria, and *vice versa*, which was strong proof that these specific curative agents found in the blood of immune animals could not be direct products of the cells. Further experiments of Pfeiffer were adduced to show that the specific nature of the curative agents militated strongly against the assumption that antitoxin was a direct product of the cells. Moreover, natural immunity was not transferable, and it was impossible to bestow bactericidal power on the blood of one animal by the introduction of an efficacious alexin from that of another. A well-recognised direct secretion of cells was therefore not transferable. Antitoxic treatment of diphtheria was the successful transference of some curative agent and this distinction between alexin and antitoxin suggested that antitoxin was some foreign matter circulating in the blood of the immune animal. He defined antitoxin and the specific curative agents found in the blood of animals immune to infective diseases as being the specific proteids of the bacteria to which immunity had been attained, modified and digested by the cells, and that whatever their chemical nature was they must be considered as derivatives from such myco-proteids, still possessing some degree of their specific nature, but with a wholly beneficent character. To regard specific curative agents as being of this nature was to find an explanation of many otherwise most puzzling facts. If the conclusions arrived at were correct it should follow that if a series of animals was taken of all degrees of susceptibility, from one possessing a natural immunity up to an animal of the most extreme susceptibility, the further removed the animal was from the condition of natural immunity the more antitoxic the serum should prove; for in the very susceptible animal no destruction but only the requisite beneficent mitigation of the poison would take place. This was one of Behring's laws. One observation that militates against this conception of

antitoxin had been reserved because the answer to it afforded a clue to the way in which it was formed. Roux discovered that if a highly immunised horse was bled, and then subsequently bled without any intermediate injection of toxin, the second bleeding yielded serum with an antitoxic value equal to that yielded by the first bleeding. He (Dr. Hunt) thought the explanation of this was to be found in the phenomenon of cumulative poisoning (as for example strychnine), and cited a paper by Metchnikoff giving the results of experiments carried out at Dorpat in support of this. The cells of the horse become accustomed to the toxin, they begin to take it up and to slowly excrete it in the form at present known as antitoxin; but this process was a constant one, and much toxin was kept stored up in the cells, so that even if no fresh introduction of toxin was made the blood might yield antitoxin for a considerable time. Finally, antitoxin had certain physical similarities to the toxin which produced it, both being precipitated by entanglement, and both soluble only in an alkaline solution.

If antitoxin was merely toxin altered and excreted by the cells, how is its action as an excito-cellular stimulus to be explained? Buchner had shown that the injection of any proteid matter, foreign to an animal organism, increased the anti-biotic power of the blood, and Rumpf obtained distinct therapeutic results in typhoid fever by the injection of the dead bacilli of blue pus. Klein also found many dead bacteria protective against cholera. He suggested as an explanation that the specific myco-proteids had a quality or disposition hostile or injurious to animal cells. This quality might consist of some particular molecular arrangement or vibration. If the cells succeeded in conquering, in digesting, this proteid poison, they would effect this by causing an alteration of such molecular arrangement. This altered arrangement being the result of a cellular effort of a particular kind, and possibly bearing the mark of that effort stamped upon it, it might be conceived that whenever this altered substance was brought into contact with cells similar to those which had bestowed the fresh molecular arrangement upon it, a cellular effort identical with that originally excited would be instantly induced.

Dr. Hunt concluded by a reference to the pathology of diphtheria, and stated that the essential factor in prognosis is the amount of damage already done before treatment is commenced. He had found an extremely early fatty degeneration of muscle structure, and in particular of the muscles having most work to do (the heart and respiratory muscles), in guinea-pigs infected with diphtheria. The early appearance of this degeneration in experimental diphtheria was very important to the prognosis of antitoxin treatment, and explained how the best results were obtained by its early exhibition and how a larger dose may be necessary, if given later, to effect the necessary excito-cellular stimulus.

CASES ILLUSTRATING THE SURGERY OF THE KIDNEY.

By J. KNOWSLEY THORNTON, M.B., C.M. EDIN.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN
AND CHILDREN, AND TO THE NEW HOSPITAL FOR WOMEN, AND
THE GROSVENOR HOSPITAL FOR WOMEN.

(Continued from p. 338.)

CASE 33.—A woman aged thirty years, single, was placed under my care by Mr. Malcolm Morris. The family history was a bad one; her father died from phthisis; her mother was alive, but sickly; two sisters were living, one sickly; all the other children, six in number, died young. The patient had been strong and healthy. Five years ago she began to suffer with pain over the left kidney, and had ever since had an attack about every six months, each successive attack being more severe than the former one. The last six months she had begun to lose health and feel unfit for her work. She never passed blood or matter in the urine. The urine examined on several occasions was normal, except that it contained a good many oxalates and a great deal of renal epithelium. There was on examination very marked tenderness over the left kidney, but I could not define the organ. The right kidney was large, smooth, and somewhat too mobile. Just

before I saw her she had begun to suffer with pain in the right side also, but it never began in the right side only when the pain in the left was severe. It was decided that I should explore the kidney, and I operated on Feb. 19th, 1890, and found a sacculated kidney, the cortex much thinned and pale, the pelvis and calyces much dilated, the ureter healthy, but so small as to be obviously inadequate. I removed the kidney, tying the vessels separately and ligaturing the ureter low down towards the bladder and dropping the stump in. The right kidney was large, smooth, and somewhat globular, but appeared to be quite healthy. The removed kidney weighed 2½ oz. This, again, appears to be a case of gradual destruction of the kidney from inadequate size of the ureter. The patient made an uninterrupted recovery, and I heard quite recently from Mr. Malcolm Morris that she remains in excellent health.

CASE 34.—A married woman aged forty-three years, the mother of thirteen children, the youngest sixteen months old, four of them dead, was placed under my care at the Samaritan Hospital by my friend and then colleague, Dr. Prickett. In the right side of her abdomen, in the situation of the right kidney, was an irregularly oval, smooth, and not very tender tumour about four inches long. She had never had any urinary trouble. The urine examined was of low specific gravity, but otherwise normal. Her father died from stone in the bladder; her mother was alive and healthy, aged seventy-four years; eight brothers and sisters were alive and well, some more had died from acute diseases. One aunt died from mammary cancer. Before the last confinement, twins, she was very large, and then first began to have pain in the right side, and when she got up noticed a lump there. I operated on May 28th, 1890, and found a sarcoma growing from the middle of the convex border of the kidney and not affecting the pelvis at all; it was apparently covered by the capsule of the kidney, and was separable from the kidney tissue, not infiltrating. Unfortunately, through press of work at the time I did not get it examined microscopically. The patient was suffering before the operation from advanced phthisis, and this was, I think, rather accelerated by the operation, and she died at the end of July with a large cavity in the left lung and the right also beginning to break down.

CASE 35.—This patient was a woman aged forty-two years, but looking much older, single, and very delicate. She had never had any serious illness till April, 1889, when she had a severe attack of influenza, which laid her up for several weeks. The pain first appeared during this attack in the right side and hip, and then, while lying in bed, she noticed a considerable swelling in that side. When she got up she suffered much pain in the back on the right side, which was increased by walking. I found a large fluctuating tumour in the right renal region, which I believed to be a hydronephrosis, and advised its removal. The operation was performed on Dec. 1st, 1890, and I could find nothing to account for the hydronephrosis. The ureter appeared quite normal in size and arrangement. I tied the vessels separately and pinned the ureter out in the lower angle of the wound. She made an uninterrupted recovery, and remains well. In 1891 she wrote to me that she was feeling better than she had done for a long time. The pathology of a case of this kind is obscure. I think there must be some abnormality in the ureter which is not recognisable when the abdomen is opened—for example, undue length leading to kink in certain positions of the body. This would, of course, become accentuated when once the pelvis of the kidney began to distend, till at last it might be so bent upon itself that no urine escaped at all. Seeing, as I now do, a large number of renal cases in consultation, I am strongly impressed with the close association of the uterine displacements with renal troubles, and I hope before long to call the attention of the profession more decidedly to this subject. I have long been convinced that many healthy ovaries have been removed for pains which were really renal or ureteral; and I am sure there is another side to the picture, and that in a certain number of cases the whole attention is fixed on the kidney when the heavy displaced uterus is the primary ailment.

CASE 36.—A woman forty-nine years of age, a widow, was placed under my care by my old friend, Sir Joseph Lister. She had ceased to menstruate suddenly seven years earlier, and then began to have hæmaturia with pain in the right

¹ The specimen was sent quite fresh to the Royal College of Surgeons of England, but unfortunately does not appear to have been examined or kept.

kidney. The attacks only came once in twelve or six months, usually without warning and at night. There were blood and clots at the end of the act of micturition, then pain in the back and the loins, with frequent micturition. I found a firm, smooth, elastic, and very mobile tumour in the situation of the right kidney, and advised its immediate removal. There were small pea-like glands in both groins. The operation was performed on Dec. 11th, 1890, and was troublesome on account of the large size of the vessels in the capsule. The renal artery and vein were also greatly enlarged, and the former had a strong thrill in its pulsation. I found one much enlarged gland behind the kidney and removed it, but it was unfortunately lost. The left kidney appeared to be quite healthy. The growth chiefly affected the front and lower end of the kidney, the upper part of the organ being large and normal. The growth was at one point clearly fungating through into a large vein or venous sinus. Small fragments from this projecting portion were like granulation tissue, and corresponded exactly with minute fragments found by Mr. Malcolm in the urine before the operation. The main mass of the tumour was firm and glistening on section, and was made up of bundles of fusiform cells, with spaces in which were masses of small round cells. The patient made a very smooth recovery, but in May, 1893, came to me complaining of pain in the right side of the head and behind the ear, with retching in the early morning, and she died a few months later with distinct evidences of secondary deposit in the brain.

CASE 37.—The patient was a woman aged forty-two years, married; it was a case of removal of a large suppurating kidney with an enormous retro-peritoneal abscess, probably tuberculous. The patient was in a very exhausted condition before the operation, with severe sweating and high temperatures, and immediately after the operation began to have offensive diarrhoea, with dark green sickness. The discharge from the drainage-tube became also quickly offensive, and she died just forty-eight hours after the operation, with a falling temperature of 99.6° F. and a rising and finally uncountable pulse and complete suppression of urine. The patient's condition before operation was such that it was merely a forlorn hope which failed. I think that the surgeon is bound to give the patient the chance if it is desired, though such cases make sad work of statistics, and make it difficult to estimate the true mortality of an operation. Cases 12 and 20 in my table² are of the same class, the latter being curiously like this case, as the patient was a married woman aged forty-two with a large perinephric abscess round a suppurating kidney, also probably of tuberculous origin, and she also died in much the same way in forty-eight hours. As I said then I repeat now, if such cases would only come to the surgeon earlier the results would be very different.

CASE 38.—A married woman aged thirty-eight years, the mother of several children, was sent to me early in 1892 by Mr. Crew of Thrapston. In the previous April she had had a sudden attack of pain in the left loin and had never been quite free from pain since, though it was sometimes more severe than at others. On talking it over with me she remembered a similar attack nearly two years before, which had come on after severe straining at stool, and lasted nearly a week. Menstruation was regular. There was no nausea or sickness and no distinct history of any hæmaturia. Before coming to me she had been seen by Dr. Ralfe, who thought she had renal calculus. The only noteworthy points about the urine were a slight trace of albumen, a few oxalates, and an excess of renal epithelium. The left kidney was markedly tender, especially towards the pelvis. It was decided that I should explore it. I operated on March 16th, 1892. The right kidney was rather large, but healthy; the left had a number of tense cysts about the size of marbles projecting from its lower end, and in its pelvis a small, hard body, which I at first thought was a stone, but afterwards found to be a similar cyst projecting into the pelvis. It was decided to remove the kidney, and during enucleation a vessel was torn and slipped back into the retro-peritoneal cellular tissue, and a large thrombus formed so rapidly that I was obliged to tie the renal vessels and ureter *en masse* and remove the kidney. I passed a rubber tube out through the loin, and there was a good deal of dark fluid oozing from it for the first forty-eight hours. She made a very

smooth recovery, but in October, 1893, she came to see me complaining of pain over the left iliac crest, with occasional throbbing exacerbations, accompanied by pus in the urine. On making a careful bimanual examination I could distinctly detect the remains of the ureter swollen and tender, and I have no doubt that it has suppurated, a condition I have before noted when I have not been able to bring the cut end up into my abdominal incision. The kidney, after removal, was found to contain a considerable number of cysts at its lower part varying in size from a large marble to a small pea, and so very tense and hard that one could easily understand that they were a constant source of pain, and that this would be likely to be increased by anything like severe straining at stool. The small cyst projecting into the pelvis was the only one above the lower third of the kidney, the rest of the organ being healthy. This case adds another pathological condition of the kidney difficult or impossible to differentiate from calculus without exploration.

CASE 39.—On March 16th, 1891, I explored the kidney of a married woman, a patient of Mr. Ray of Dulwich. She had long suffered with abdominal pains in various situations, and before I saw her Dr. John Williams had removed her ovaries, and Mr. Durham had operated for a curious warty condition of the vaginal mucous membrane. When I first saw her at Mr. Ray's request I found her very ill in bed, with high temperature, rapid pulse, much emaciation, and constant pain over the left kidney, with occasional severe exacerbations down the ureter, and she was passing the most horribly offensive urine I have ever seen, loaded with blood and pus. The warty condition of the vagina had also returned and there were occasional hæmorrhages from it. I came to the conclusion that she was suffering from pyelitis, and that it was probably from calculus, and that the stone was very likely in the ureter. The latter condition was suggested by the fact that while passing the horribly offensive and bloody urine she would suddenly pass a specimen or two quite clear and acid. It was, therefore, decided that I should explore the abdomen. I found two minute stones embedded in the ureter rather more than half-way down; they were both quite small and very angular, the lower one being the larger one, and this probably accounted for the long stick they had made. They were quite immovable, and as it would obviously be extremely dangerous to open the ureter for their removal with the knowledge of the fetid material penned up behind in the kidney, and the husband was not prepared to assent to the removal of the kidney, I closed my incision, the hope being that they might still gradually find their way into the bladder. We waited a little over a year, and her condition was then so extremely grave that it was decided that I should remove the kidney, leaving the stones in the ureter to take care of themselves, as in Case 19, already recorded, in which the stone in the ureter never gave any serious trouble after removal of the kidney. On proceeding to operate on March 31st, 1892, I found that the stones had moved down fully an inch, and that, instead of being close together, there was now a slight space between them. The operation was prolonged by the separation of a good deal of omentum and a coil of small intestine which had adhered to my former incision. The anæsthetic was also very badly taken, the patient being several times in great danger; special care was also necessary in enucleating the kidney in view of its foul contents. This was accomplished satisfactorily, and the vessels ligatured and divided apart from the ureter; and I was then able to extract the kidney from the abdomen, attached only by the ureter, the division of the latter being made altogether outside the abdomen. I carefully cleaned the opened end with a strong solution of corrosive sublimate, and then pinned it out through a small hole in the skin of the loin. When I was sponging out the peritoneum I found a coil of gut firmly adherent to the under-surface of Dr. John Williams' colporrhomy incision and thought it advisable to free it. This was only accomplished by long and careful dissection, and the patient was on the operating table two hours and a quarter. She made a good recovery, and, as I had hoped, the warty condition of the vagina rapidly subsided when it ceased to be irritated by the foul urine. There was such a mass of hard, cracked, and bleeding warty tissue on the anterior vaginal wall near the urethra that it might well have been thought to be malignant disease. The after-history of this case has not been so satisfactory as I could have wished; there have been periods of good health, but from time to time suppuration

² Transactions of the Royal Medical and Chirurgical Society, vol. lxxii.

evidently occurs in the remains of the ureter above the calculi, and when the pus is discharged into the bladder a condition of things is produced almost as bad as when the kidney was still in work.

THE PRESYSTOLIC APEX MURMUR OF AORTIC REGURGITATION: WITH NOTES OF A WELL-MARKED EXAMPLE.

By THEODORE FISHER, M.D. LOND.,
REGISTRAR TO THE BRISTOL GENERAL HOSPITAL.

A LOW-PITCHED presystolic murmur may occasionally be heard over a small area immediately around the impulse in cases of aortic regurgitation. The high-pitched, blowing, diastolic murmur is possibly audible from the base to the apex and even outwards into the axilla, but just at the point of the heart's impulse a rumbling sound takes its place. Such a low-pitched sound will probably be made to disappear by slight pressure of the stethoscope, and may thus be overlooked. Cases, however, have been recorded by Austin Flint, Gaiteras, Gairdner, Osler, Maguire, Lees, and others in which a more or less well-marked presystolic apex murmur was present where aortic valve disease was the only heart lesion. The following case is an example of that curious occurrence of the murmur. In this instance the presystolic bruit was not low-pitched and rumbling, but of that loud, rolling character that reminds one of the sound produced by a flapping sail as it is filled by a puff of wind. Well marked though the murmur was, the mitral orifice proved to be of natural size.

CASE 1.—A man thirty-two years of age was admitted into the Bristol General Hospital on Aug. 28th, 1894, under the care of Dr. George Parker, who has kindly given me permission to publish the case. The patient was a thin, wiry, rather short man. He was markedly cyanosed, and although there was no orthopnoea he was in great distress. He generally lay on the right side with his head resting upon his right forearm, but quickly rose to the sitting posture at the onset of a frequent short cough. There was slight oedema of the legs, but no swelling of the abdomen. The history was interesting, but need not be given here; it may, however, be mentioned that he apparently had not had rheumatism, and there was no evidence of syphilis. The heart's impulse was in the fifth space in the nipple line, where it was accompanied by a distinct presystolic thrill. The cardiac dulness was very slightly increased on the left, but was well marked at the fourth and fifth spaces to the right of the sternum, extending about two inches outwards in the latter space. There was a loud presystolic apex murmur of rolling character, which increased in intensity as it approached an abrupt termination. Although, however, the termination was abrupt and loud the first sound was not distinct, and the notes state: "There is nothing that can be called a first sound; what appears to be the first sound has a broken character." The area over which the murmur was well marked was small and situated immediately around the impulse, but a duller rolling sound was heard more widely. In addition to this murmur a *bruit de galop* was heard in a somewhat unusual position below and outside the impulse. Three separate sounds were there distinctly audible. There was no systolic murmur at the impulse, but between that point and the sternum a high-pitched systolic bruit became audible, and was heard from the fifth to the second right and left spaces. A diastolic murmur of high-pitched blowing character was audible down the left of the sternum. Behind the sternum another murmur, loud and half-squeaking, half musical, was sometimes heard. This the patient said that he had noticed. The pulse was regular, 100 small, but aortic in character (see Chart). The patient steadily grew worse and died on Sept. 24th. Nothing fresh of importance developed except moderate effusion into the right pleura, which was twice aspirated. On the day of death it was noticed that a systolic murmur was audible at the impulse, and that the triple sound formerly heard outside the apex had disappeared.

Necropsy.—At the post-mortem examination the situation of the apex was found to be at the sixth rib

in the nipple line, and the right auricle extended three inches to the right of the sternum. The pericardium was healthy. The heart was enlarged and weighed twenty-two and a half ounces, the enlargement being mainly in the left ventricle, the wall of which measured from three-quarters to seven-eighths of an inch in diameter. There was comparatively little dilatation. The mitral valves were perfectly healthy, and the orifice of normal size. It measured four inches. The tricuspid valves were also healthy. The orifice measured four inches and a half. The main feature of interest was in the aorta. Immediately above the valves the vessel was surrounded by a raised area varying in breadth from three-quarters to one inch and a half. The upper border was serpiginous and the surface irregular and pouched. The post-mortem examination did not take place until forty-four hours after death, and the thickened area was deeply blood-stained, but seen earlier it would no doubt

Pulse tracing.

have presented the grey appearance of the aortitis generally attributed to syphilis. The aortic valves were slightly thickened, but only one, the right posterior, was deformed, and that was retroverted. The endocardium over the septum ventriculorum was greatly thickened where the regurgitant stream had impinged. The orifices of the coronary arteries were not obstructed and the vessels themselves were quite healthy. The heart muscle looked normal and the portion microscopically examined showed no pathological changes. Microscopic sections of the affected aorta gave evidence of active disease. There was fibroid thickening of the greater part of the intima and media, but groups of leucocytes were scattered through the outer half of the vessel and through its sheath.

Remarks.—In this case a well-marked presystolic murmur and a presystolic thrill existed in association with incompetence of the aortic valves, but with a perfectly normal mitral orifice. It is now well known that the physical signs of mitral stenosis may occasionally be present in cases of disease of the aortic orifice; and in examining the records of a large number of cases of death from various forms of heart lesion at Guy's Hospital I discovered several more or less well-marked instances of a presystolic apex murmur where the aortic orifice alone was affected. The following single example may be briefly referred to by kind permission of Dr. Hale White.

CASE 2.—A man forty-five years of age was admitted into Guy's Hospital under the care of Dr. Hale White in 1892. The heart's impulse was in the sixth space, three inches outside the nipple line. There was a presystolic thrill at the apex, and the notes state: "There is a harsh presystolic murmur at the point of impulse in the sixth space. At the base there is a to-and-fro murmur." The pulse was "solashing," being 92 to the minute.

Necropsy.—At the post-mortem examination the mitral orifice was found to measure four inches and a half, and the valves were quite normal. The aortic valves were also quite healthy; but there was pouching of the sinuses of Valsalva, with dilatation of the first part of the aorta, which led to regurgitation through the aortic orifice. There was a thickened patch of endocardium on the septum ventriculorum where the regurgitant stream had impinged. Dr. E. W. Goodall, then medical registrar, adds a note at the end of the clinical report. He says: "As regards the presystolic thrill and bruit, they were marked, and mitral stenosis was diagnosed as existing. The thrill and bruit may perhaps be accounted for by Austin Flint's hypothesis."

Remarks.—There is one point of morbid anatomy I should like to draw attention to in this case and in the one that precedes it—that is, the situation of thickened endocardium upon the septum ventriculorum showing the point of impact of the regurgitant stream. This is of some interest since it negatives the explanation Dr. Sansom has suggested for the presystolic murmur of aortic regurgitation. He has thought it probable that the regurgitant stream, impinging upon the anterior mitral flap, may set up vibrations that lead to the production of the presystolic sound.

These two cases show that the regurgitant stream need not be directed upon the valve, and one other case that may be briefly noticed seems to show that a presystolic murmur may exist in association with aortic valve disease without any regurgitation being present.

CASE 3.—A man aged forty-seven years was twice admitted to Guy's Hospital under the care of Dr. Pavy in 1879, and on both occasions a presystolic apex murmur was noted by different clinical clerks. The medical registrar also heads the report: "Well-marked presystolic bruit." At the post-mortem examination, however, the mitral orifice was found to admit four fingers. The aortic valves were adherent half way up their edges, but were considered by Dr. Goodhart to have been competent. Allowing Dr. Goodhart's conclusion to be correct, it is obvious that not only need the regurgitant stream not impinge upon the anterior flap of the mitral valve, but that no regurgitant stream need be present for the production of a presystolic apex murmur.

This leads us to a form of presystolic murmur in which I am somewhat interested, a murmur occurring in dilatation of the heart in which neither mitral stenosis nor aortic disease is present, but the most common lesion is adherent pericardium. A paper upon this subject was read by me at the last meeting of the British Medical Association. A copy of this paper sent for abstract to a foreign journal fell into the hands of the conductors of the *Medical Press and Circular*, and was published by them without my knowledge in the number for Oct. 10th, 1894. That being the case, I must refer any interested reader to that periodical for detailed information. Brief notes of twelve cases of diastolic or presystolic apex murmur occurring without mitral stenosis or disease of the aortic valves are given. Ten of them are from the Guy's Hospital records. Of the twelve cases, in eight the pericardium was universally adherent, and in only two the pericardium was healthy. In five other cases of general adhesion of the pericardium a presystolic apex murmur was heard, but they have been excluded because the pathologist thought the aortic valves probably incompetent. The existence of a presystolic murmur in the above cases was noted not only by the clinical clerks but also in the majority of instances by the physician or medical registrar. Thus, Dr. Goodhart adds marginal notes in two instances. In one, a girl aged eleven years in whom the mitral orifice was found to measure four inches, he describes "a distinct presystolic thrill and a rumbling, long, diastolic murmur in the fifth and sixth spaces." In another case, a boy aged nine years, where the orifice measured four inches and a half, Dr. Goodhart mentions "a short, roaring, diastolic sound," and calls it "a diastolic mitral." Dr. Frederick Taylor also noted a large diastolic thrill and a diastolic rumbling sound where the mitral orifice was perfectly normal. Dr. Pye-Smith and Dr. Hale White both diagnosed mitral stenosis incorrectly from the presence of a presystolic murmur, and Dr. Newton Pitt also noted a presystolic apex murmur where the mitral orifice measured four inches and seven-eighths.

In all these cases there was adhesion of the pericardium. It is therefore evident that there are two entirely different pathological conditions that will give signs simulating those of mitral stenosis—namely, disease of the aortic orifice and adherent pericardium. Such being the case, it is reasonable to conclude that some condition common to both must be concerned in the production of the murmur. The most obvious feature is dilatation of the left ventricle, and it may be supposed that the mitral orifice is small compared with the size of that cavity and thus produces a virtual stenosis. The large size of the orifice, however, in some of the cases of adherent pericardium excludes the possibility of such an explanation, and curiously enough it was in those forms of heart disease in which a virtual stenosis probably exists that, with one exception, I failed to find instances of a presystolic apex murmur having been noted. I refer to cardiac dilatation due to chronic Bright's disease, and to less definite but probably not infrequent causes such as alcohol and overwork. Since we reject a virtual stenosis as an explanation we must consider what other conditions may be present in a dilated left ventricle. It may have been noticed in the post-mortem room that when a dilated ventricle is present the large anterior flap of the mitral valve may be held taut by columnæ carneæ and chordæ tendinæ that have not fully shared in the dilatation. During life, as the ventricle becomes filled during diastole this state of tension must be present in the large mitral flap, which, held out in the moving blood currents instead of falling against the

septum, may be left free to vibrate. Dr. Stacey Wilson in his interesting lecture upon Dilatation of the Right Side of the Heart gives a similar explanation for the diastolic murmur sometimes heard over the right ventricle.¹ On endeavouring to accept such a view we, however, again meet with difficulty. If such an explanation were correct one would expect a presystolic apex murmur to be common in dilatation of the heart from any cause and especially in those cases of dilated heart in which the mitral valves remain healthy—for example, those consequent upon Bright's disease and other causes affecting the heart muscle. In the Guy's Hospital records for twenty years one instance only, however, was discovered in cases of that nature, and that, curiously enough, was a well-marked example. It was in a man aged forty-six, admitted three times, and on every occasion mitral stenosis was diagnosed. The last admission was under Dr. Pavy in 1879. At the post-mortem examination a large heart was found but no definite cause for hypertrophy discovered. The mitral orifice admitted three fingers. The absence of mitral stenosis struck the medical registrar—I think Dr. Mahomed—who heads the clinical report: "Presystolic bruit heard in this case, but no stenosis found." Although a presystolic murmur was noted in the above case of cardiac dilatation in which neither adherent pericardium nor disease of the aortic orifice existed, we are obliged to admit that it is a remarkable exception, and that there is virtually no evidence to prove that simple dilatation of the heart will give rise to a presystolic murmur. That being the case, we are driven to consider whether there is anything else in common between enlarged hearts due to disease of the aortic orifice and to adherent pericardium. Possibly in both the innervation may be affected. In the pericarditis that precedes adhesion of the pericardium it is difficult to understand how the nerves coursing superficially over the bloodvessels can entirely escape, and in cases where aortic regurgitation is due to aortitis, causing dilatation of the aortic orifice, the nerves passing downward in the sheath of the aorta may possibly be affected, as Lanceraux has long believed. In Case 1, for example, leucocytes scattered through the sheath of the aorta were often aggregated around the nerves, and although it was not evident that the nerves had materially suffered, toxins may have been present and have caused functional disturbance. In cases, however, where the rumbling apex murmur is associated with disease of the aortic valves and not of the aorta we can hardly suppose that any affection of the nerves is present, yet the frequency of cardiac pain suggests that in some obscure way the innervation of the heart is affected or that the heart muscle is functionally disturbed. The first case in which I heard a presystolic murmur that was proved to have been unassociated with mitral stenosis, the cardiac failure was of the nature that seems to me to point to disturbed innervation. In a boy aged nine, without œdema or liver enlargement, there was orthopœa, great distress, and a rapidly acting heart beating with sufficient force to cause visible vibration of the whole body. On recently looking again at the microscopic sections of the heart muscle pathological features previously overlooked were noticed—viz., some proliferation of the endothelial cells of the pericardium and groups of leucocytes in the subserous tissue. In other words, the boy appears to have died in a very early stage of pericarditis. Since there is no evidence of myocarditis we may suppose that death occurred from functional disturbance of the nerves of the heart muscle or by toxins. Allowing that in some cases of presystolic murmur occurring without mitral stenosis there is a deranged nervous mechanism or some unusual alteration in muscular action, the question of the mode of production of the murmur still remains to be explained. Possibly there is a loss of muscular tone and vibrations of the muscle wall are set up by the inrush of blood on contraction of the auricle. But whatever the explanation of the murmur may be the fact remains that mitral stenosis is not the only heart lesion that will give rise to a presystolic murmur.

In closing, reference may be made to a case that Dr. Perry has kindly given me permission to mention. This case presents an additional feature of interest in that it bore resemblance to some cases of mitral stenosis in another particular. Of every four cardiac beats only two were felt at the wrist. The case was a woman aged twenty who was admitted under the care of Dr. Wooldridge

¹ THE LANCET, Sept. 15th, 1894.

in August, 1888. She had been seen by him as an out-patient, when a well-marked presystolic murmur and a soft systolic murmur were present at the apex. After admission, however, the presystolic murmur seems to have disappeared and a diastolic murmur was audible between the nipple and the sternum. In August, 1892 the patient was again admitted under the care of Dr. Perry. Over the mitral area a "rough rumbling presystolic murmur" was then heard, as well as one systolic and more blowing in character. A presystolic thrill was also present. As already mentioned, it was thought that only two pulsations were felt at the wrist to every four cardiac beats, and sphygmographic tracings seemed to support that view. The patient died.

The clinical clerk gives an abstract of the result of the post-mortem examination, after which he somewhat cautiously remarks: "The diagnosis of mitral constriction that was fairly confidently made in the ward was thus proved to be apparently a mistake." The heart was a peculiar one; it was large, weighing eighteen ounces. The apex was formed mainly by the right ventricle, which was greatly hypertrophied, the muscle wall measuring three-quarters of an inch in diameter. The tricuspid orifice measured five inches and the mitral three inches and three quarters. The aortic valves were healthy, but the pulmonary had a few small vegetations upon them. The most curious feature was the marked atheroma of the pulmonary artery, which extended into its small branches. Apparently the hypertrophy and dilatation of the right ventricle were due to obstruction in this vessel.

The case affords fresh evidence of the possibility of the existence of a presystolic murmur apart from mitral stenosis, but apparently does not throw much light upon the production of such a murmur. In all probability the murmur was produced in the right ventricle, and the great thickness of the wall is worthy of note—a feature one would think must have been in some way connected with the production of the abnormal sound. Common though a dilated right ventricle is, a rumbling sound sufficiently loud to attract the attention of most observers is rarely heard in association with such dilatation. A previous suggestion has, however, been made—namely, that disturbed innervation enters into the etiology of these anomalous murmurs. Possibly the curious and extensive atheroma present in the pulmonary artery in this case followed an arteritis that had affected all the coats of the vessel and its sheath, leading to injury of some nerves of the cardiac plexus.

Since writing the above Dr. Audeoud of Geneva has kindly sent me his paper upon "Le Rétrécissement Mitral Fonctionnel." He has noticed diastolic and presystolic apex murmurs which have disappeared. Dr. Audeoud speaks of a functional stenosis which he considers to be due to temporary spasm of the mitral orifice. The results of necropsies in two cases are given. One of the cases resembles one under Dr. Perry above mentioned. In a man aged sixty-two in whom a diastolic apex murmur had been present nothing was found but a large heart. The mitral orifice admitted three fingers, and the valves were healthy.

NOTE ON "THE SURGICAL SIGNIFICANCE OF SMALL CALIBRE RIFLES."

By BRIG.-SURG.-LT.-COL. W. F. STEVENSON, A.M.S.,
PROFESSOR OF MILITARY SURGERY, ARMY MEDICAL SCHOOL, NETLEY.

THREE very valuable and interesting articles on the above subject have recently appeared in the *United Service Gazette*.¹ They are based on a paper by Lieutenant H. R. Stiles, Assistant Surgeon, United States Army, which appeared recently in the journal of the Military Service Institution, New York, and presumably the views put forward in them are those held by that officer.

In the first article Lieutenant Stiles' opinion of the cause of the occurrence of those frightfully lacerated and destructive injuries produced by rifle bullets at short ranges, to which the term "explosive effects" is commonly applied, is stated. He considers that they are to be explained by what has been called by Continental surgeons the "hydraulic theory." Upholders of this theory of the production of these

extensive injuries look upon a limb or a part of the body as a sealed vessel containing liquid, or an almost liquid substance, and consider that when it is penetrated by a projectile possessed of high velocity, the liquids of the tissues produce within it similar effects to those seen in a tin can filled with water or a moist substance, and sealed, under like circumstances. In the latter case the bullet produces, besides the entrance and exit holes, numerous ruptures in the sides and in the top and bottom of the vessel quite unconnected with the actual perforations due to the bullet itself. The edges of these rents in the metal are turned outwards, and it is evident that they are the result of some powerful agency acting from within other than direct impact of the bullet. Here, no doubt, the "hydraulic theory" is sufficient to account for what is found; the enormous additional pressure suddenly exerted by its fluid contents in all directions on the inner surfaces of the closed vessel causes ruptures to occur at the points of least resistance, and this pressure expends itself in all directions. Naturally, therefore, it is found that ruptures are as likely to occur on the entrance side as on any other, whereas "explosive effects" on living tissues are almost confined to the exit side of the part struck. To account for these injuries by the aid of this "theory" is to overlook the simpler explanation and to adopt the more complex one. If the sudden increase of pressure on the liquids of the part penetrated by the bullet were the cause of the great disorganisation found in these cases it should be expected that the destruction would be most marked up and down the limb—that is, on either side of the direction of the bullet track; but quite different conditions are always found. "Explosive effects" are very seldom seen except where bone is traversed by the bullet. Delorme states that they are very exceptional where soft parts alone are implicated, and both cases are open to the same explanation. When a rifle bullet produces these so-called "explosive effects" on living tissues the track it makes is somewhat funnel-shaped, and that portion of its course from the aperture of entrance to the near side of the bone represents the tube of the funnel and from that point to the exit side represents the expanded portion of the funnel. In its passage through the soft parts, where the resistance it meets with is but slight, it makes a track apparently of less diameter than its own; but from the point at which the bone is fractured, and where real opposition is first met with, splinters and fragments of the harder substance are driven forwards with enormous energy acquired from the projectile, and proportional to the amount which the latter has lost, and these, as well as the particles of the soft tissues and even of the fluids themselves, act as secondary missiles on all the parts in their immediate vicinity, causing destruction in ever increasing severity until the exit side is reached, where it is greatest. Fragments of bone are driven violently forwards, and escape at the exit wound or through the other rents in the skin made by their passage; muscles and tendons, nerves and vessels protrude from the exit wound, which itself may be almost of any dimensions, whilst the seat of fracture is quite cleared of fragments, showing considerable loss of substance between the broken ends. Splinters are also often found embedded in the muscles and other soft tissues at some considerable distance. The destructive effects of the bullet are seen to have been expended in a direction mostly corresponding with its forward motion, not upwards and downwards, and on the entrance as well as on the exit side, as would have been the case had they been due to hydraulic pressure, and as is seen to occur in the experiment on the tin can filled with water. In a word, the so-called "explosive effects" seen in rifle-bullet wounds produced at short ranges are due directly to the projectile and indirectly to the action of the particles of the tissues themselves (bones, soft parts, and liquids), which are driven forwards with great velocity, and possessed, therefore, of great energy and destructive power. This view is held by Sir Thomas Longmore.² In like manner, Delorme states that too much importance has for many years been attached to the hydraulic theory in this connexion; it does account, he says, for extensive injuries in the hollow viscera (bladder, stomach, intestine, heart); here it is indisputable: "but in the case of solid organs filled with liquids (brain, spleen, liver, kidneys) it is not the sole cause, because, for these latter, it is necessary to have great regard for the effect of the solid particles projected forwards. For the other soft tissues it has no importance whatever."³ Paul Bruns has directed his attention

¹ Dec. 29th, 1894, and Jan. 5th and 12th, 1895.

² Gunshot Injuries, p. 127.

³ Chirurgie de Guerre, vol. ii., p. 996.

to this matter and has made numerous experiments. He also, while upholding the "theory" to a great extent, makes the very similar remark that "until lately too much importance has been given to it." One of Bruns' conclusions is that "the destructive effects of hydraulic pressure on the human tissues are greater as the walls surrounding them are stronger." In cases of head injury by rifle bullets it is probable that the "theory" is sufficient to explain the numerous fractures found. When a bullet perforates the cranium the bony sutures are found to have been burst apart and fissures are seen extending in all directions, many of them being quite unconnected with the apertures of entrance and exit. The brain being practically a liquid, the skull is in this case in a similar condition to that of the experimental tin can, and precisely similar results are produced. This is well shown in a specimen lately presented to the museum of the Army Medical School, Netley, by Surgeon-Colonel R. V. Ash. A Lee-Mitford bullet, accidentally discharged, perforated a soldier's head at four yards range. Numerous and extended fissures, the great majority of which were not connected with either aperture, traversed the calvarium in all directions, and the sutures were separated. In this class of case the "hydraulic theory" is no doubt the correct explanation of the violent bursting apart of the bony covering of the almost liquid brain; but in all other cases "explosive effects" are due to the action of the particles of the tissues themselves propelled forwards as secondary missiles. Lieutenant Stiles states that "there must be moisture present to bring about explosive effects." Delorme, on the other hand, shows that this condition is not a necessity, for it is seen when a bullet at the highest rate of velocity is fired into such absolutely dry substances as a block of lead or a book; and Bruns points out that the greater the deformation a bullet is capable of undergoing in its passage through the tissues the more extensive are the explosive effects produced by it. He therefore concludes that as bullets with hard metal envelopes seldom deform against human tissues, so this severe class of injuries will be less often produced by the modern projectile than was the case when only soft leaden ones were used.

In the second article the differences which Lieutenant Stiles has observed in the wounds produced at various ranges by the new rifle about to be introduced into the United States army (one of 0.3 calibre) are detailed. His experience quite agrees with that obtained in this country and on the Continent with very similar weapons, and his record is a valuable addition to our previous knowledge of the subject. He alludes to the curious fact that, whereas the amount of injury produced in bone by small-calibre, hard-mantled bullets steadily decreases as the range increases (and the velocity and energy of the bullets lessen), up to 2000 yards, at distances beyond this range "the new bullet loses a little of its favourable character, and extensive fissuring and comminution again begin to appear." He suggests that the reason of this is that, as at these extreme ranges the bullet is travelling over the most inclined portion of its trajectory—as it is, in fact, falling more nearly perpendicularly—it strikes an object more obliquely and with more of its side, and therefore with a larger area of its surface; and again he says: "The ball has lost the greater part of its progressive velocity at these ranges, whilst its velocity of rotation is as great as ever; a torsional effect is thus produced by the ball, and increased splintering is thus brought about." The first of these two explanations for the unexpected increase of bone injuries at extreme ranges may be accepted as possible and even probable; but as regards the second this cannot be said. There is a direct and constant relation between the motions of translation and of rotation of rifle bullets—as the former is rapid or slow so is the latter. This must be so, for the velocity of rotation depends upon the speed at which the bullet travels up the barrel of the rifle. Both motions steadily decrease as the bullet travels along its course, and both probably cease at about the same time. The unexpended spin of the bullet when it lodges would be far more likely to cause comminution of bone at shorter ranges than at very extreme ones. But there is another explanation which may be considered, one which tends to show a greater probability of bullets striking objects at very long ranges with their sides—that is, with larger surface areas. It has been found that a modern rifle bullet, because of its great length as compared with its weight and diameter, commences to wobble towards the end of its flight, and has a motion comparable with that of a peg-top when its spin is nearly expended—that is, that its long

axis rotates round a point somewhere behind its apex. The effect of this would, of course, be to permit it to strike an object with its side, and therefore with a larger surface of impact. This may possibly be considered as effective in producing an increase of splintering and comminution at long ranges, when the opposite condition might have been naturally expected, had not experience demonstrated its existence.

The "surgical significance" of the new rifle is summed up in the third article. "It [the modern bullet] produces clean-cut, slightly lacerated wounds of soft parts, exerts less explosive action, and splinters and displaces bones less (except at short ranges); its wounds offer the best possible conditions for rapid and perfect healing, being small, clean-cut, and aseptic as a rule, but they are prone to bleed freely and at once." These conclusions are very favourable to the new bullet from the humanitarian point of view, but it is an open question whether or not Lieutenant Stiles' account of the bone injuries produced by it, and detailed in the second article, bears them out. Undoubtedly simple wounds of the soft parts do heal rapidly; but in the others the damage from the extensive fissuring and comminution is most severe, and considerable actual experience will yet be required before we can know the value of Bruns' statement that "the new arm of small calibre is not only the best, but also the most humane, in that it lessens the horrors of war as far as possible." At the same time, it cannot be denied that our earlier conclusions on this subject, derived from experiments on horses made both in this country and in France, did give us exaggerated notions of the effects of small bullets on animal tissues. The extent and severity of a bullet injury are always in direct proportion to the resistance the missile meets with, so long as it has sufficient energy to overcome that resistance. In drawing conclusions from the experiments on horses the far greater strength of their bones over that of human bones was not properly allowed for, and experience has now shown that they were incorrect. Actual wounds on living men and experiments on dead bodies made by Lagarde in America and by others on the continent have proved this. Another class of experiments from which inaccurate ideas were formed was that of firing at human bodies at fixed ranges with reduced charges, the amount of powder in the cartridges being calculated so as to impart to the bullet the velocity it would have at any desired actual distance. M. Demosthen, an army surgeon, has made experiments with the new weapon of the Roumanian Army—a Mannlicher rifle of 6.5 mm. (about 0.26 in.) calibre, the bullet of which is composed of a core of hardened lead covered with a plated steel envelope, firing at human bodies at actual ranges with full service charges, and the results were different from those obtained by the other method. M. Demosthen's report was published and presented to the Paris Academy of Medicine in 1894. It contains much evidence that bone injuries produced by a small bore under the ordinary conditions of its use are more severe than those seen when reduced charges are had recourse to. Demosthen says that the shafts of long bones are fractured with much splintering and comminution, and this at long as well as short ranges, for he found but little difference in this matter between one humerus hit at 1400 metres and another at 100 metres; that the statements of Bruns, Habart, Seydel, and others that long bones may be expected to show clean-cut perforations without actual fracture at such distances as from 1000 to 1200 metres are not correct; that simple tunnelling of even the epiphyses of long bones is exceptional, and that he has never seen it occur at ranges under 600 metres; that in 65 cases of fracture of bones (human) of all sorts, at ranges of from 5 metres to 1400 metres, he has never seen simple perforation without fragmentation and splintering; and, finally that the clean-cut character of wounds in vessels is in favour of severe hæmorrhage even when only small arteries are injured. Demosthen does "not hesitate to admit his difficulty in agreeing with those who are disposed to accord a humane character to the modern projectile." "Wounds of the head, of the chest, of the abdomen, and of the long bones fail to bring into prominence this attribute in connexion with it." Another point, the importance of which must in future be acknowledged, is the impossibility of carrying out the regulations now existing in European armies regarding "first assistance" in the field. Under present arrangements (working so close to the fighting line) the medical personnel would themselves soon be in as great need of help and surgical treatment as those they went out to succour.

Speaking of wounds of the abdomen, Lieutenant Stiles remarks that these will be the most fatal ones produced by the modern bullet. No doubt they will be very fatal ones; but as experiment has shown that the perforations made by it in the intestines are similar to those made in the skin—small, clean-cut, and less in diameter than the bullet itself (about one-third of an inch)—they will on this account be all the more suitable for the only treatment which can offer any hope of success in cases where penetration is found to have occurred—viz., laparotomy with a view to suture of intestinal wounds and of controlling hæmorrhage, which in this situation shows peculiarly little tendency to cease spontaneously. Delorme points out that the minuteness of the intestinal perforations will be favourable to successful suture. Wounds of the lung also may be expected to show better results of treatment. In the late Chilian War, where a small-bore Mannlicher rifle was used, these gave a lower mortality rate than any previously observed. A comparison of statistics of the numbers of killed and wounded in battle when smooth-bore muskets were used with those experienced in later campaigns since rifles were invented might, at first sight, lead one to imagine that the more far-reaching and accurate the military weapons become the fewer will be the number of casualties which occur. The killed, wounded, and missing in the English army after Waterloo amounted to 23 per cent., while in many of the important fights during the war of 1870-71 this ratio came as low as 4 per cent. to 13 per cent. But Lieutenant Stiles rightly remarks on this question that trustworthy statistics of casualties in battle should in these days be based only on the ratios of killed and wounded to the numbers of those actually engaged and under fire. In former days, taking the whole strength of the armies as the basis, the calculation was accurate enough; but latterly this has not been the case, because the forces present have been so large that they were not all engaged, and the percentages of casualties have therefore been apparently smaller. Guessing at the probable numbers of killed and wounded in future wars is mere waste of time, but we may rely on the general truth of the statement that the proportion of casualties amongst those actually engaged will be greatly increased.

The articles in the *United Service Gazette* were probably written by a surgeon, and they would have been much more useful to our profession if they had appeared in a medical journal. They are able contributions to our present knowledge of an interesting subject about which little is known from actual experience. The strictly surgical matter in them is, for the most part, in agreement with the opinions of the best authorities of the day.

CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

By C. H. GEOFFREY RAMSBOTTOM, M.B., CH.B. VICT.,
LATE SENIOR RESIDENT MEDICAL OFFICER TO ST. MARY'S
HOSPITAL, MANCHESTER.

I RECENTLY had an interesting case of hepatic disease which appears to me to have been one of acute yellow atrophy of the liver, although I am sorry to say I could not gain permission to verify my diagnosis by a post-mortem examination. About a month ago the patient consulted me; he was a tall, slimly built man with a slight stoop, and sixty years of age. He presented rather a wasted appearance, his cheeks were hollow and his eyes sunken; he was of a despondent, timid temperament and altogether gave one the impression that he had a somewhat serious affection. He consulted me on account of some diarrhoea, pain after taking food, and flatulence; otherwise he stated he was well. There was no history of hæmatemesis or melæna, although he stated he had vomited some "green matter." Physical examination revealed nothing beyond his lean condition, a flatulent distension of the abdomen, and a slight hepatic enlargement. His pulse was rather slow and feeble, and he seemed generally debilitated. I considered that the above condition was due to dyspeptic troubles and treated him accordingly, and planned a dietary for him. In about five days he told me he was better and that he thought he would go to the seaside for a rest. A week or ten days elapsed, when he sent for me hurriedly one morning. I examined him again thoroughly, and found the liver on this occasion rather less than normal,

and the stomach appeared to be somewhat dilated. His temperature was normal, the pulse 80 and weak, and the abdomen distended, but only with flatus. He complained of slight headache and drowsiness with slight pain in the hepatic region. His bowels were constipated. On the following day he vomited everything that was given to him. There was pain in the hepatic region upon pressure; he was restless and irritable. The temperature was 100.5° F. and his pulse 90. The tongue was dry and furred brown. The vomiting was eased on the following day only by peptonised milk diet; he was still constipated and slightly delirious at night; there was a slight tinge of jaundice. The temperature was 101° and the pulse 110. The stools were of a clay colour, mixed with a little blood. On the next day (the fourth of acute onset) the patient was decidedly weaker. The liver dulness had further diminished; and jaundice was fairly well marked. The temperature was 99.5°; the pulse still rapid, but feebler. He was in a semi-somnolent state and very delirious at night. On one occasion he jumped out of bed and dictated incoherent commands respecting Parliament, local boards, business, &c. A little ascites was now detectable and also some oedema of the legs. The urine contained a small quantity of blood, bile, and leucin and tyrosin. The patient gradually became weaker, refused all food except a little wine and beef-tea, and the last day or two had periods of a comatose state alternating with those of a low muttering delirium; on the morning of the eighth day from the acute onset he was in a comatose condition, with stertorous breathing and abdomen retracted, and died on that day. The liver dulness in the mammary line was about one inch and a half.

The above case seems to me to have been one of acute yellow atrophy of the liver, but there were never any convulsive twitchings or epileptiform convulsions. There were no petechial hæmorrhages under the skin, and the pulse was quick throughout; the jaundice was never so very well marked and there was no history of poisoning by phosphorus or arsenic. He had reasons for mental worry.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DEFICIENT DEVELOPMENT OF AN UPPER EXTREMITY IN CONSEQUENCE OF PRESSURE EXERTED UPON THE AXILLARY VESSELS AND NERVES.

By W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO GUY'S HOSPITAL AND THE HOSPITAL
FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE patient, a woman aged twenty-one years, had a number of exostoses about her body. These had apparently ceased to increase in size. Two bony growths were felt projecting from the inner aspect of the upper part of the shaft of each humerus, that on the right side being small and inconspicuous, while the one on the left side was long and prominent, and caused her so much discomfort and limitation of movement that she was desirous of having it removed. She was admitted into Guy's Hospital under my care. The piece of bone was narrow and elongated, measuring about one inch and a half in length. It was so placed that it carried the third part of the axillary vessels with the branches of the brachial plexus forward in advance of the position they normally occupy. Any moderate amount of pressure on the upper aspect of the growth controlled the circulation in the arm and caused a sensation of numbness and pain in it. It seemed that in some positions of the arm enough pressure was exerted upon the vessels and nerves to render the arm and hand cold and numb. This took place frequently when she was asleep. How much of this was due to pressure on the vessels and how much to pressure on the nerves I was unable to decide, but both structures appeared to suffer. Her arms were said to be of equal length up to eight years of age. She first noticed the presence of the exostosis on the left side at twelve years of

age, and since that period it had grown steadily and had caused her progressive pain and discomfort, both locally and by the disturbance of the circulation and innervation of the whole upper extremity. When she was sixteen years of age it was found that the left arm was shorter than the right by about an inch, and that it was also less developed muscularly. At the present time the difference in measurement is more than 1½ in. The measurement of the right arm from the acromion to the external condyle is 10½ in., while on the left side it is 9½ in. From the external condyle to the styloid process of the ulna on the right side there is an interval of at least 8 in., and on the left side about 7½ in. The length of the right ring-finger is 3½ in., and of the left 2½ in. The circumferences of the right arm and forearm are respectively 9½ in. and 8 in., and of the left 9¼ in. and 7½ in. Though the power which could be exerted by the several muscles of the left arm was slighter than that possible on the right side, the deficiency was proportional to their difference in development, and to the fact of the affected arm being the left one. There was no evidence of any paralysis of the part.

St. Thomas's-street, S.E.

SEVERE VOMITING ACCOMPANIED BY TETANY.

BY GEORGE WALTER BARBER, M.R.C.S., L.R.C.P. LOND.,
SURGEON P. AND O. SERVICE,

I AM induced to send this account of the following case after reading in THE LANCET of Oct. 20th Dr. Soltan Fenwick's cases of tetany described by him at the London Clinical Society.

At Aden on Sept. 4th, 1894, a man came to me complaining of neuralgia in the temporal region (right). He had felt unwell during the last few days, and had had diarrhoea for two days, which he ascribed to the excessive heat of the Red Sea. This evening the diarrhoea became severe, with abdominal cramp, but was completely stopped by thirty grains of aromatic powder of chalk. On Sept. 5th the patient began to vomit, and this was accompanied by tetanic spasms lasting from five to ten minutes, affecting the abdominal recti, the upper extremities (the elbow being slightly flexed, the forearm adducted, the hands bent on the wrist, and the fingers flexed and pressed into the palms with the thumbs), and the lower extremities (the foot being extended on the leg and in a position of equino-varus, and the toes being flexed). These paroxysms occurred just before and during the vomiting of a little bile-stained fluid every fifteen minutes, and were attended with free perspiration. The face was cyanosed and the breathing hurried. The heart, lungs, abdominal viscera, optic discs, and patellar reflexes were normal. The urine was diminished and high coloured; there was no albumen or sugar. Effervescing mixtures with morphia and also a large dose of bromide were tried without avail, and nothing was retained on the stomach. On Sept. 6th the paroxysms continued, and the pulse was weak and irregular. Everything by the mouth was stopped, and I gave beef-tea and brandy enemas every four hours, and injected half a grain of morphia in two doses at intervals of two hours. The temperature was 101° F. The abdomen was painful and tender. On Sept. 7th the paroxysms occurred at intervals of an hour and were not so strong. The patient slept a little. The temperature was normal and remained so. A quarter of a grain of morphia was injected. On Sept. 8th the patient still vomited, but the spasms had stopped. The facial appearance and the pulse were better. An enema of soap, twice repeated, was followed by a copious, dark, fetid motion. Twenty grains of sulphonal powder were given to obtain sleep. On Sept. 9th the vomiting and spasms both stopped. A small amount of milk and soda was allowed every two hours. Twenty grains of sulphonal powder were given. After this the patient made an uninterrupted recovery with the exception of a crop of boils. On Sept. 15th he was allowed full diet and given tonics, and on Sept. 23rd he resumed duty. He has never had any symptoms of gastric ulcer and showed no signs of dilatation of the stomach, but had a very similar attack four years ago, lasting eight days, while voyaging between Calcutta and Aden.

Brindisi.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

LONDON HOSPITAL.

TWO CASES IN WHICH SMALL SUPPURATED OVARIAN CYSTS WERE EASILY ENUCLEATED AND REMOVED ENTIRE.

(Under the care of Dr. HERMAN.)

AT the present time with ordinary antiseptic precautions the operation of removal of simple ovarian cysts has become practically almost free from risk, but when suppuration has occurred in the cyst the danger from sepsis is much increased. The formation of extensive adhesions greatly interferes, as a rule, with the removal of the tumour, and the operation is thereby rendered exceedingly difficult. In the cases reported below, though suppuration had existed in the cysts for a lengthened period, in the first case probably for many years, it was found possible to shell out the cysts from their surrounding adhesions without rupture. The small size of the cysts may have contributed somewhat to the ease with which they were removed. The final result in each case was extremely satisfactory, and sufficient time has elapsed since the operation to enable us to feel sure that the cure is permanent. For the notes of the first case we are mainly indebted to Dr. H. G. Lys, formerly resident accoucheur.

CASE 1.—The patient was married on July 23rd, 1871, at the age of eighteen. She had had good health until her marriage. For the first six weeks after her marriage she was quite well, but did not menstruate. She then had violent shooting pain in the lower abdomen, which swelled; she vomited, and there was vaginal hæmorrhage lasting three or four weeks. She was then in the London Hospital, at first under one of the general physicians and then under the care of the late Dr. Head. The abdomen got smaller, hæmorrhage and vomiting ceased, and she left the hospital well. The records of this illness have not been preserved. After this she became pregnant, and was delivered of a living child on Jan. 26th, 1873, after an instrumental labour. She got up on the tenth day, but fainted, and had to go to bed again. She was in bed six weeks with what the medical man in attendance called "inflammation and low fever," its chief symptom being pain in the lower abdomen. She did not go out for three months. At the beginning of April, 1874, she was again seized with violent pain in the abdomen, which was tender, and in May she was again in the London Hospital under the care of Dr. Head. Notes were then made to the effect that there was a hard firm mass surrounding the uterus and fixing it, and that there was a profuse discharge from the os uteri, after which the uterus became more movable. The diagnosis then was "pelvic cellulitis." In February, 1876, she came back to the hospital, stating that she had been getting ill for six months, with wasting, pain in the lower abdomen, pain on defecation, and dyspareunia. She was admitted under the care of the late Dr. Palfrey. She went out only a little better, and then became an out-patient under the care of Dr. Herman. On Nov. 13th, 1876, a note was made that there was "a distinct tender mass to the left of the uterus." She attended for many months without much improvement. On Jan. 5th, 1880, she again came to the hospital, stating that in April, 1879, she had had another acute illness, keeping her in bed seven weeks. Since the illness in 1874 she had never menstruated without pain, and had been always in more or less pain. In 1885 she had another acute attack, laying her up for three months; but for this she did not come to the hospital. Soon after this she became a widow. In November, 1888, she fell down on her back, and this was followed by aggravation of her customary pelvic pain, which brought her to the hospital. She was admitted on Nov. 17th. On Nov. 20th it was noted that the uterus was fixed, that there was a hard lump to the left of it, and some thickening to the right. The possibility of cure by operation was now put before the patient by Dr. Herman, but she, thinking of the many years her ailment had lasted,

was unwilling to run any risk for a possible, but not certain, cure. She left the hospital on Dec. 18th, being somewhat better for her stay in it. Early in 1889 a prospect of re-marriage offered itself to her, and this brought her back to the hospital, anxious to have anything done which could put her in health. She was admitted on March 4th, 1889, and on March 8th Dr. Herman opened the abdomen. On passing the fingers down and tracing outwards the left uterine appendages, a piece of tissue was detached and brought up through the wound; it looked like a piece of cyst wall. Passing the fingers down again Dr. Herman was able to detach, lift out of its bed, and bring out a cyst the size of a large walnut. It was very tense and contained pus. There was no hæmorrhage. There was no disease of the Fallopian tubes appreciable by the fingers except thickening of the peritoneum over and around them. The patient recovered without any bad symptoms and went home well on March 27th. In January, 1895, it was noted that the patient had attended at the hospital from time to time since the operation to report her condition. She had been quite well ever since. She had remarried, but had had no sign of pregnancy. She had menstruated regularly and without pain. There was no dyspareunia. She had gained flesh, and her appearance was in striking contrast to her worn and emaciated aspect during the years of illness.

CASE 2.—A woman aged twenty-five was admitted into the London Hospital on April 3rd, 1889. She first menstruated at thirteen; the flow was moderate in quantity and from the beginning attended with pain. Since the age of eighteen the pain had been so bad as to lay her up for a day or two each month. For the last three or four years she had had fainting fits during the day of menstruation on which the pain was at its worst. For the last twelve months she had had pain in the inter-menstrual period as well as during menstruation. She was married at twenty. Dyspareunia had been present from the beginning, and for the last twelve months had been very severe. Six months previously to admission she had had a thick yellow discharge, which began a week after menstruation had ceased and lasted a fortnight, then getting better. Her appetite had been bad for twelve months; there had been nausea and often vomiting. She had lost flesh. She was anæmic, and complained of shortness of breath, pain in the chest, and cold hands and feet. She slept badly, being kept awake by the pain, which for the last five weeks had been continual and worse at night. On examination the vaginal portion of the cervix was found to be quite absent, the os externum being flush with the vaginal wall. The uterus was fixed by induration on each side of it. On the left side there was a distinct lump, extending from the uterus to the pelvic wall. The patient was much wasted. She was kept in bed, and laxatives and counter-irritation were employed; but after twenty-four days of this treatment the pain was not at all better, the lump was not smaller, and the patient's general condition was not improved. Therefore, on April 27th Dr. Herman opened the abdomen. The uterine appendages on both sides were found to be embedded in adhesions. The right ovary and tube were separated and removed. The tube was thickened and studded internally with warty growths. In attempting to free the uterine appendages on the left side a cyst about the size of a hen's egg was separated, being shelled out of its bed without difficulty and without hæmorrhage. It was brought out entire, and when cut open was found to contain thick pus. Nothing else was removed on this side. A drainage-tube was put in (Dr. Herman now thinks that this was unnecessary). The patient recovered without hindrance, except that the track of the drainage-tube continued to discharge for three months, when a ligature came away, after which the sinus healed. On this account she was longer than usual in the hospital, which she left on July 9th. She came back to report herself in April, 1890. She was fat, and had a good colour. She menstruated regularly, and had no pain either during or between menstruations. There was no dyspareunia. The patient remained in perfect health until January, 1892. She then began to suffer from great pain in the abdomen and back and down the left leg. She lost flesh and again became anæmic. She was readmitted on May 13th, 1892. Her aspect and behaviour showed that her pain was severe. The abdomen was tender. The uterus was fixed, and there was a swelling on each side of and behind the uterus. She was kept in bed, and medical treatment was used without any improvement either in the symptoms or general condition until June 7th, when an aspirator needle was put into the part of the

tumour which closest approached the vagina; but no pus was extracted. She still did not improve, and on June 17th Dr. Herman again opened the abdomen. The bowels above the pelvic brim were found to be matted together by adhesions; and on separating these a collection of pus, thought to be in the broad ligament, was opened in front of and to the left of the uterus. This was emptied of pus and a drainage-tube put in. For about a month after this operation the patient improved. There was free discharge from the wound, the pain got better, and the patient gained flesh. Then, as the wound healed, she began again to complain of pain and to lose flesh, and the evening temperature to rise, ranging from 100° to 101.5° F. Cystitis developed, culminating in the passage by the urethra of a slough of the mucous membrane of the bladder on Aug. 18th. On Aug. 30th some pus was passed with the feces. Pain, wasting, and slight fever continued although the cystitis got better, and as there was still a mass behind and on each side of the uterus, and pus from time to time came away with the feces, Dr. Herman on Oct. 18th made a free incision with scissors through the vagina behind the cervix, and then with the fingers broke down the tissues so as to thoroughly open up the broad ligaments. No distinct cavity or large collection of pus was opened into. The cavity made was stuffed with iodoform gauze. This operation was followed by rapid improvement. The temperature afterwards did not exceed 100°. No more pus was passed by the bowel. The pain ceased. The patient gained flesh rapidly, and she was discharged well on Nov. 13th. She last reported herself at the end of 1894. She was then fat, florid, free from all pain, and considered herself as in all respects quite well.

Remarks by Dr. HERMAN.—These two cases are both alike in that in each there was a small suppurated cyst in the ovary, very loosely connected to its bed, and easily shelled out without hæmorrhage. This is an unusual form of ovarian suppuration, and they are the only cases of the kind that I have seen. In such cases as this the simplicity of the operation makes it not more dangerous than the removal of normal ovaries. The first case shows how very chronic suppuration in the ovary may be. There can be little doubt that the recurrent attacks of pelvic inflammation and the persistent pain between them were due to the continued presence during fifteen years of the disease discovered and removed by the operation—viz., an ovarian abscess. It is a gratifying illustration of the progress in our therapeutic power. At the time the patient was in the London Hospital, under Dr. Head and under Dr. Palfrey, chronic suppuration in the uterine appendages had never been either diagnosed with any certainty or cured, and in diagnosing this case as pelvic cellulitis, and treating it by expectant methods alone, these two physicians applied the knowledge of the time; but had our present knowledge been available this patient might have been cured then. It is to be regretted that many lists of operations on inflamed uterine appendages contain so little information as to the after-history of the patients. Ovarian suppuration is due to the entry of microbes: if these have got to the ovary by way of the tubes some may remain in the stumps of the tubes; if through the broad ligaments inflammation-producing matter may remain in them. It is known that in a certain proportion of cases pelvic inflammation recurs after inflamed tubes and ovaries have been removed. For this reason I did not immediately publish the above cases. In the second of them it seems to me probable that the ovarian cyst was infected through the cellular tissue in the broad ligament, and that the subsequent suppuration was a residual abscess. It is in such cases as this, in which the broad ligament is riddled with suppuration, that the Continental practice of removing the uterus (Péan), or the uterus and appendages (Leopold and Landau), seems to have some justification; but it seems to me to be possible, as in this case, to open up by the vagina and drain pelvic suppurated cavities, even when multilocular, without removing either the uterus or the ovaries.

BASINGSTOKE COTTAGE HOSPITAL.

A CASE OF LAPAROTOMY; REMARKS.

(Under the care of Dr. C. F. WEBB.)

WHEN, after the reduction of a hernia, symptoms suggestive of obstruction occur the treatment to be followed presents some difficulties. In the following case the symptoms were very indefinite; they never amounted to those of strangulation, a little nausea and slight distension being

all that could be observed; yet, though the constriction had apparently not yet become sufficient to cause much interference with the circulation in the herniated bowel, at the operation it was felt to be tense, and the peritoneal coat of the intestine had been damaged. The displacement of the testis was an interesting complication. The only operation admissible under the circumstances was a laparotomy, as thereby the bowel could be much more easily got at than by any incision over the site of the hernia.

A man aged forty years was engaged as a waiter on the evening of Oct. 31st, and while in the act of stretching across a table to lift a tray of glasses felt a sudden sharp pain in the left inguinal canal. He put down the tray and placed his hand on the spot, and found that an old hernia which had not protruded for several months had again come down. At once, in great haste, he, to use his own words, "squeezed it all up," which caused him considerable pain and slight faintness. He afterwards felt sick and went home. On arriving at his house the bowels acted freely for the second time that day, and while adjusting his dress he noticed that the left testicle was not in its usual position in the scrotum, nor could he feel it anywhere. He was first seen on Nov. 1st, and complained of bilious vomiting with nausea and some retching, not severe, and took only water. There was no meteorism, no collapse, no suppression of urine, and very trifling pain, with no local tenderness. The inguinal canal, which was large, easily admitted the finger, but no trace of the testicle could be found. On Nov. 2nd there were no fresh symptoms. There was very slight pain occasionally radiating towards the umbilicus. The patient had slept well. The urine was normal and in good quantity. On the 3rd there was very slight distension, no pain, no sickness, and no tenderness. The patient had passed no flatus since the evening of Oct. 31st, but said he felt very well. On the 4th he was free from pain, and slept soundly. The urine was normal, the pulse was good, the tongue was slightly furred, not dry, and there was no distension, and no sickness or nausea. On the 5th there was no sickness, pain, or tenderness, and rather more distension; the urine was normal, the pulse good, the patient was taking iced milk and complained of hunger. On the 6th there was no sickness, pain, or tenderness; the urine was normal and the pulse good, and the patient said he felt very well. On the 7th at 9 A.M. there was considerable nausea, but no vomiting or retching; the patient slept well, urine was passed in quantity, there was no pain, the pulse was good, and there was no tenderness. Dr. Webb here determined to wait no longer, but performed laparotomy. Accordingly, at 10 A.M., chloroform alone being administered and the catheter passed, the abdominal wall was carefully washed and afterwards swabbed with a perchloride of mercury solution (1 in 1000). An incision, commencing just below the umbilicus and carried downwards to the extent of three inches, was made in the mesial line down to the linea alba, all bleeding being arrested by torsion. The linea alba was divided on a director, and the peritoneum in the same manner. On passing into the wound two fingers of the left hand considerable matting of the intestines was found towards the left iliac fossa, and so firm was this that great difficulty was experienced in reaching the fossa. It being found necessary to introduce the whole hand, the wound was enlarged and the hand introduced, which encountered below the internal abdominal ring on the left side a large oviform swelling. On following the bowel towards this swelling it was found that the bowel was continued on into it, and on further examination a tight, tough stricture was found; this was divided, and from eight to ten inches of bowel were gently drawn out. On examining this portion of the bowel at the spot where the stricture had grasped it the peritoneal coat was found to be peeled off to the extent of an inch. A chromicised gut suture was put in to strengthen the bowel. On passing the fingers through the opening that had constricted the bowel the testicle was found below the internal abdominal ring, and was carefully replaced in the ring and gently passed down the inguinal canal to the scrotum. The wound was dressed in the usual way. The bowels acted naturally on the fourth day. The catheter had only to be used on the fifth and sixth days. Delirium was present on the seventh and eighth days. The bowels continuing to act once or twice a day, he made an uninterrupted recovery, and was convalescent on the twentieth day.

Remarks by Dr. WEBB.—This case is peculiar in that so

long a portion of intestine was strictured with so very few bad symptoms, and that the force used in returning the hernia was so great that the bowel was burst through the hernial sac and the testicle pushed clear of the internal abdominal ring at one and the same time. It also illustrates well how useless it is to trust to even favourable symptoms when grave injury of some kind has happened to the bowels, and how important it is to explore as early as possible.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Annual General Meeting.

THE annual general meeting of this society was held on March 1st, the President, Mr. HUTCHINSON, being in the chair.

The report of the council was read. In order to increase the usefulness of the society the following changes in connexion with the method of accepting papers and publishing the Transactions have been adopted:—1. Papers accepted for reading are thereby accepted for publication, either in the Transactions or in the Proceedings, as may be determined by the council. 2. Papers will be printed before being read, and be obtainable (in proof) on application at the society's rooms. 3. Fellows may read their own papers. 4. The Transactions are to be published in three parts (in paper covers) during the year—viz., on Feb. 1st, May 1st, and Aug. 1st—as well as annually (bound as heretofore); and Fellows are free to choose in which form they will receive them. 5. Papers are to be issued separately for sale (by the society only) as early as possible after the issue of the part, at a price to be affixed to each. 6. Some of the ordinary meetings are to be devoted to discussions and demonstrations on special subjects, to be introduced by a short paper or papers by Fellows of the society, or others, at the request of the council.

The alterations in the by-laws rendered necessary by these changes were submitted for confirmation. The council trusted that these changes would be appreciated by the Fellows, and would attract a larger number of communications on subjects of immediate interest from authors who hitherto might have hesitated to present their work to the society in consequence of the lengthened period that had often elapsed between the reading and the publication of papers.

The honorary librarians reported that the library had never before been so largely used. A new supplement to the catalogue had been issued, which contained all the books added to the library during the year 1893, and also some donations of tracts and books which had been received during the building operations, and which it had been impossible to catalogue during that busy time. During the year 526 new books and pamphlets had been added to the library exclusive of the large number of volumes of periodicals. The first volume of the report of the Committee on Climatology and Balneology was in the press, and would shortly be published by Messrs. Macmillan. This volume included the medical climatology of the south coast of England and the Channel Islands and the more important mineral springs and baths of England and Scotland. It was proposed that a second portion of the report should deal with the climatology of the remainder of England and Wales and also of the minor spas.

The honorary treasurers reported that the finances of the society were in an improving and thoroughly satisfactory condition. The whole of the expenses incurred on account of building, altering, and moving into the present premises had now been paid off, with the exception of the small sum of £20, which had been retained as a guarantee for the due fulfilment of a contract. The roll of the society now contained the names of 503 resident Fellows, 279 non-resident Fellows, and 17 honorary Fellows.

The PRESIDENT then delivered his annual address. Alluding first to the late Sir Andrew Clark's scheme for the organisation of an Academy of Medicine, he said that his ambition for the society did not soar so high, and he thought that neither the smaller societies nor the Royal Medical and Chirurgical Society itself would be the gainers by the proposed amalgamation. It was also open to doubt whether it would be wise, as

wished by some, that the society should become a power in the State. He himself thought it would be better to leave questions of medical education and medico-legal problems to such bodies as the Royal Colleges, the General Medical Council, the British Medical Association, and the medical press. While he was glad to congratulate the society on their present position, which was more satisfactory than of old in spite of the greater expenditure, yet it could not be denied that there appeared to be a diminution of interest in the meetings. This was in part due to the springing up of new societies which had cultivated specialist topics and offered a specialist audience. In order to adapt the society to the changing conditions of the times the new regulations detailed above had been framed. Pre-arranged discussions on topics of interest would be held, the exhibition of patients and specimens encouraged, and the detailing of new facts would be hoped for quite as much as the expression of opinion and criticism. Certain topics of great general interest might thus come up which otherwise might not be brought forward in an original paper. Arrangements might possibly be made with sister institutions in other cities by which their members would, when visiting London, have an equal footing with the Fellows of the society. The President then proceeded to allude to the losses the society had sustained by death during the year. Two honorary Fellows had passed away—Hannover and von Helmholtz. Among the six ordinary Fellows were the names of Barnard Holt, an ingenious practical surgeon; of Octavius Sturges, whose works on pneumonia and chorea were classics; and of John Whitaker Hulke, whose varied powers, clear judgment, and uprightness of character caused him to be held in high estimation by his colleagues. The fact that many were taken from us before their full time should cause us to lay to heart the uncertainties by which we were surrounded, and so live our lives without hurry but without loitering, that if death cut short an unfinished career we should leave our wealth of knowledge on record, and thus what we had toiled to gain would not be lost to our heirs. In a literary sense those who had been mentioned had made their wills, and posterity would realise their generous bequests.

The following were elected to serve as officers during the ensuing year:—President: Jonathan Hutchinson, F.R.S. Vice-Presidents: Charles John Hare, M.D., John Harley, M.D., J. Warrington Haward, and John Langton. Honorary Treasurers: William Selby Church, M.D., and John Ashton Bostock, C.B. Honorary Secretaries: John Mitchell Bruce, M.D., and Robert W. Parker. Honorary Librarians: Samuel Jones Gee, M.D., and Rickman J. Godlee, M.S. Members of Council: Francis Charlewood Turner, M.D., Frederick Thomas Roberts, M.D., Frederick Taylor, M.D., Felix Semon, M.D., William Ewart, M.D., John Hammond Morgan, Arthur Edward J. Barker, Reginald Harrison, Frederick Treves, and Thomas FitzPatrick, M.D.

The usual votes of thanks to retiring officers closed the proceedings.

PATHOLOGICAL SOCIETY OF LONDON.

The Pathology of Diphtheria.

AN ordinary meeting of this society was held on March 5th, Dr. PAVY, President, being in the chair.

Dr. BERTRAM HUNT introduced a discussion by his paper on the Pathology of Diphtheria which we print in another place (p. 604).

Dr. HAYWARD had found hydrocele fluid a most useful nutrient medium for cultivating the diphtheria bacillus. He had first been led to adopt it on account of the difficulty in preparing good ox serum tubes free from the discolouration produced by diffused hæmoglobin, and to save the inconvenience of attending slaughter-houses and removing the collected serum, a proceeding which involved much waste of time and energy in the absence of skilled attendants, and when only small quantities were required from time to time. In preparing the fluid it was drawn off into a sterile flask and decanted into tubes, and these were subjected to a temperature of 55° C. for a period of three or four hours on three successive days, the tubes in the interval being kept in the warm chamber at 37° C. This method of fractional sterilisation had been found quite satisfactory. Finally, the tubes were placed on the slant in the hot air incubator and kept at a temperature of 65° or 69° C.; in a short time the fluid coagulated, forming a pale, greenish-yellow,

almost transparent, and sufficiently firm medium. At a higher temperature the albumen was thrown down in white, flaky masses. The diphtheria bacillus grew readily on this solidified hydrocele fluid; small white colonies appeared within twenty-four hours; the maximum growth was attained in three or four days; the colonies were not so large as those grown on serum; the bacilli retained their characteristic form and virulence. The special advantage of hydrocele fluid rested in the fact that it was inimical to the growth of many of the organisms found in diphtheritic membrane, hence the labour of recognising the bacillus and obtaining pure subcultures was rendered easier. *Streptococcus pyogenes* grew on this medium, but *staphylococcus albus* and *aureus* had not been recognised, although growing abundantly on nutrient agar tubes inoculated from the same membrane. Not infrequently pure cultivations had been obtained directly from the membrane. Experiments were quoted to illustrate the relative growth of a mixture of diphtheria bacilli, streptococcus pyogenes, and staphylococcus respectively on hydrocele fluid, serum, and nutrient agar, and comment was made on the infrequency of suppuration after tapping for hydrocele in the days before aseptic surgery. Dr. White had greatly simplified and accelerated the preparation of the hydrocele fluid by a method which he described. (*Vide infra*.) As regarded its use it was claimed: 1. It was easy to obtain and prepare, and formed a clear, firm, solid nutrient medium. 2. The diphtheria bacillus grew readily upon it, and could be recognised within twenty-four hours. 3. It was inimical to the growth of many of the organisms found in diphtheritic membrane, and thus rendered a separation of the bacillus easier. On antitoxic horse serum, obtained by Dr. Klein's permission from the Brown Institute, it was found that the bacillus grew readily if tubes were prepared by Dr. Lorrain Smith's method, which involved sterilisation at a high temperature. If the serum was rendered solid by mixture with 2 per cent. agar, the temperature not being raised above 40° C., the bacillus grew very feebly, no definite colonies appearing in streak cultures within forty-eight hours; but both in the fluid and solidified antitoxic serum it remained active at least for three days (and subcultures were made which grew readily on other media). An experiment was quoted which appeared to show that the antitoxic serum retained its property of protecting guinea-pigs even when the serum had been inoculated with the bacillus and incubated for forty-eight hours. It was suggested from this that the antitoxin when injected in diphtheria could have little or no effect *per se* on the membrane or the bacillus; it must either neutralise directly the chemical products formed or by acting as a stimulus to the natural antagonistic forces at work render the best of all charitable aid in helping the tissues to help themselves. Remarks were also made on cases in which the bacilli had been detected in membrane occurring on the conjunctiva and in the stomach; on the clinical significance of different varieties of the bacillus and its association with other micro-organisms; and on the length of time during which its presence could be detected after disappearance of the membrane.

Dr. C. POWELL WHITE referred to the cultivation of bacillus diphtheriæ on hydrocele fluid. He said that in October last he undertook the bacterioscopic diagnosis of the cases of diphtheria admitted to St. Bartholomew's Hospital. Hearing from Dr. Hayward of the use of hydrocele fluid as a culture medium for the diphtheria bacillus, he, at Dr. Kanthack's suggestion, applied to it the method introduced by Dr. Lorrain Smith for solidifying blood serum, and published by him in 1894.¹ This method consisted in adding to the medium a certain proportion (for ox serum it was 0.1 to 0.15 per cent.) of caustic soda, and afterwards heating the tubes in a sloping position in the autoclave to a temperature of 120° C. for at least twenty minutes. After several trials he found that the amount of caustic soda to be added to the hydrocele fluid was about 0.07 (0.06 to 0.09) per cent. The exact amount must be determined for each specimen by trial tubes containing 10 c.c. each of the fluid. The caustic soda was used in the form of a 10 per cent. solution. The resulting medium was as clear as nutrient gelatine. On this medium the bacillus diphtheriæ grew better than any of the organisms usually associated with it. He had obtained a distinct growth after only seven hours' incubation. Streptococci grew on it, but much more slowly than the diphtheria.

¹ Brit. Med. Jour., June 2nd, 1894.

bacillus. *Staphylococcus aureus* grew very slowly on this medium, and did not produce its yellow pigment. In order to separate the bacilli he inoculated one of these tubes directly from the false membrane. Examination eighteen to twenty hours afterwards revealed the presence of the diphtheria bacillus, often without any associated organisms. The advantages of this hydrocele fluid medium were—(1) it was (in hospital practice) easy to obtain; (2) it was perfectly transparent; and (3) it was especially suited for the separation of the diphtheria bacillus.

Dr. KANTHACK showed a specimen of Diphtheria Bacilli found in the alveoli of the lung in a case of diphtheritic broncho-pneumonia. He remarked on the rarity of finding the diphtheria bacillus so far down; for in the alveoli in these cases streptococci alone were usually found. Another specimen showed the presence of active phagocytosis in a guinea-pig which had been acutely infected with diphtheria. The guinea-pig died within twenty-four hours and nearly every leucocyte was found filled with diphtheria bacilli. This showed that phagocytosis was not the sole explanation of immunisation, though it was a phenomenon of it. If the animal body were able to neutralise the poison generated by the bacilli it would live, notwithstanding the presence of the bacilli themselves. In discussing these questions of immunity it was necessary not to generalise too much; the same process was not true of all diseases. He agreed with Dr. Hunt as to the specificity of the immunising serum. If the bacillus prodigiosus was itself injected into the peritoneal cavity immunisation not only against that bacillus but also against other organisms would be conferred. But if, on the other hand, instead of the bacillus itself the serum of the immune animal was injected, then immunity would be conferred only against the bacillus prodigiosus alone. From this it followed that it was not right to argue in the reverse direction. For instance, we could not say that because the serum of a patient recovered from cholera would immunise against a vibrio of cholera that therefore that vibrio was the cause of the disease. The serum of certain naturally immune animals could confer immunity on others. Metschnikoff had shown that it was easy to immunise against a living bacillus, but it was often difficult to immunise against its toxine: it was certainly not easy to immunise an animal against pure tetanus toxine, and it was extremely difficult to immunise an animal against pure cobra poison. From the animals inoculated with cobra poison he had not yet succeeded in obtaining an immunising serum, though it was stated that this had been obtained by others. The albumoses were first investigated in England by Hankin; the name tox-albumen was not a good one, because the albuminous or proteid matter could be removed from the poison—they should rather be called toxines or tox-albuminoids.

The debate was then adjourned till the next regular meeting of the society on March 19th.

CLINICAL SOCIETY OF LONDON.

Unusual Case of Diphtheria in the Air Passages.—Case of Malformation of Heart, with Hæmophilia.—Case of Gangrenous Umbilical Hernia; Successful Resection with use of Murphy's Button.—Hysterical Contracture of Legs.

AN ordinary meeting of this society was held on March 1st, Mr. LANGTON, Acting President, being in the chair.

Mr. LANGTON said that his presence in the chair indicated the loss the society had sustained by the death of Mr. Hulke, who was an original member. The late President, strong in individual personality and convictions, was a many-sided man and an able and successful worker in many branches of science. He was singularly wanting in self-interest. The profession had lost a cultivated and learned surgeon, the Clinical Society an able and wise President, science an ardent and enthusiastic worker, and the world a Christian gentleman actuated in all things by a high standard of duty. Mr. Langton added that he had been nominated by the council as senior surgical Vice-President to act for the remainder of Mr. Hulke's term of office.

Sir DYCE DUCKWORTH, in moving the subjoined resolution, recorded his own sense of the loss the profession had sustained by Mr. Hulke's death. The late President showed modesty combined with fearlessness; he had strong opinions, and had the courage of them when occasion required. The resolution, seconded by Dr. GLOVER, and carried *nem. con.*,

was as follows:—"This meeting desires to record its sense of the great loss the Clinical Society of London has sustained by the death of its President, John Whitaker Hulke, F.R.S. One of its original members and serving on its first council, he helped to start the society on its successful course, and from its formation to the present time Mr. Hulke has taken a leading part in its scientific work. His fourteen papers in the Society's Transactions are of lasting value, and they testify to his keen critical faculty, great learning, and wide experience; while his many interventions in the discussions of the papers of others never failed to add greatly to the value and interest of the meetings. As President of the society he was uniformly courteous, sagacious, and unfailing in the prompt and punctual discharge of all his duties. In him the society has lost not only its President, but one of its chief supporters and most brilliant ornaments."

Dr. GOODALL read a paper on an unusual case of Diphtheria in the Air Passages. The patient was a boy aged four, who was admitted into the Eastern Hospital with faucial diphtheria. On the ninth day after admission he expectorated a cast of the trachea, and during the next week he brought up several casts of the trachea or bronchi and several shreds of membrane. There was albuminuria lasting for about a month. At the end of three weeks from admission paralysis of the palate, ciliary muscles, and lower extremities supervened. The boy recovered and left the hospital quite well at the end of another seven weeks. The point of interest in the case was that, in spite of the extensive formation of membrane in the trachea and large bronchi, there were never signs of laryngeal obstruction. Only during the expulsion of the largest casts was there dyspnoea. It was reasonable to suppose that in this case the larynx was unaffected. Three somewhat similar cases had come under his observation—a boy aged four, a girl aged four, and a young woman aged eighteen. All were in the first instance cases of faucial diphtheria. The young woman died, after having expectorated several casts of the trachea. There was no dyspnoea, and she apparently died from the severity of the disease. The Klebs-Löffler bacillus was found in the faucial exudation. The two children coughed up casts of the trachea, but had no symptoms of laryngeal obstruction. Both were subsequently paralysed and both recovered.—Mr. W. G. SPENCER said that the cases related were interesting in that they showed that cases of plastic bronchitis in children were identical in origin with diphtheria and ought to be classed as such. He remarked that it was unusual for a boy aged four to cough up shreds of membrane, and inquired if the Klebs-Löffler bacillus were found in the first case.—Dr. SIDNEY PHILLIPS said that occasionally cases were seen in which casts were coughed up with but few signs of obstruction, the latter symptom not being present because the casts were so loosely attached. In plastic bronchitis the casts could be seen to be laminated under the microscope and were quite different from diphtheritic membrane. The clinical course of plastic bronchitis was also different and the condition might continue for years.—Mr. SPENCER added that he was referring to some museum specimens of casts from children.—Sir DYCE DUCKWORTH said that plastic bronchitis was a disease attacking middle-aged or elderly people and could not be confounded with diphtheria. The casts of plastic bronchitis were difficult to find and required much searching for. They involved the smaller bronchi, and this explained the asthmatic symptoms and paroxysmal cough. He believed that plastic bronchitis did not occur in children at all.—Dr. SANSON said that patients with plastic bronchitis frequently suffered from profuse hæmoptysis, which, in addition to the other symptoms mentioned, served to differentiate this disease from diphtheria.—Dr. GOODALL, in reply, said that he did not look for the bacillus in the first case, but it was followed by typical paralysis.

Dr. LEE DICKINSON recorded a case of Malformation of the Heart associated with Hæmophilia. The patient was a girl aged eight with pronounced congenital heart disease and hæmophilia, and Dr. Dickinson asked how far these diseases were related. He reviewed the opinions held in the early part of this century as to a developmental connexion between cyanosis and hæmophilia, and regretted the obsolescence into which they had fallen. A hæmorrhagic tendency had often been noted in cases of malformation of the heart, and was sometimes partly explainable by venous congestion or venosity of the blood; but in cases like the one brought forward, without either clubbing of the extremities or cyanosis, there was an unequivocal hæmorrhagic diathesis. Some degree of

malformation of the heart had been found in a few cases associated with hæmophilia, but apart from this the two diseases might be related in a developmental peculiarity of the blood. There were exact observations to show that the blood in congenital heart disease was in a state of concentration, especially as regarded the number of red corpuscles, which might explain its cyanosis; and there was reason to suppose that in hæmophilia the blood was in a somewhat similar state.—Dr. SANSOM questioned whether the case could be correctly called hæmophilia. The patient was a female child with signs of cardiac anomaly—probably a perforation of the inter-ventricular septum without pulmonary stenosis—and the hæmorrhage might be explained by the cardiac lesion. Cases of hæmophilia were very rare in the female, hæmophilia usually following the male line. The pathology of the affection was obscure, but in one case a condition of the arterial walls was observed which might be termed imperfect muscular adaptation.—Sir DYCE DUCKWORTH remarked that, though hæmophilia was much commoner in males, yet females might be the victims of it. He did not think that children with morbus cæruleus were more liable to bleed than others.—Dr. SIDNEY PHILLIPS inquired if any other members of the family suffered from hæmophilia.—Dr. DICKINSON, in reply, said that the cardiac condition was not severe enough to explain the hæmorrhages, for the child was never cyanosed. There was no family history of hæmophilia.

Mr. GILBERT BARLING (Birmingham) read notes of a case of Gangrenous Umbilical Hernia in which a successful result followed Resection with use of Murphy's Button. The patient, a female aged forty-nine years, was admitted to the Birmingham General Hospital four days after strangulation commenced. On the day of admission the symptoms ceased suddenly. The strangulation was caused by a severely constricting band which involved about five inches of small intestine, and the upper or entering portion was gangrenous at the point of constriction. The patient's general condition being good, the strangulated gut, with a V-shaped piece of mesentery, was removed, and the divided ends of the intestine approximated by a Murphy's button one inch in diameter. Recovery was uneventful, but the button was not passed until the twenty-fourth day, two days after the patient had been allowed to get up. It gripped a ring of necrosed gut.—Mr. PEARCE GOULD remarked that though the gut had been tightly strangulated for three days, yet it was not associated with signs of marked collapse. He asked if the pulse was soft, if the features were blue, the extremities cold, or if there was any distension of the abdomen. The occurrence of this condition at the umbilicus was more favourable than at the inguinal or femoral rings, for the gut could be more readily delivered and the necessary manipulations could be more easily performed. There was a great tendency for these artificial communications to become narrowed. He asked if there was any evidence that the indigestion which the patient had complained of could be due to the lodging of the button at the ileo-cæcal valve.—Mr. LANGTON admitted that certain disadvantages attached to the use of these buttons, but he had also seen stenosis after enterectomy when end-to-end approximation had been done and when Senn's plates had been used.—Mr. BARLING, in reply, said that the good condition of the patient accounted for the success of the operation. The difference in the results of these cases as recorded by different surgeons was perhaps partly due to a different appreciation of the term "gangrene of the gut," and then again patients reacted to infection in a widely different manner. There was no distension of the abdomen because the obstruction was high up. The indigestion occurred on the fourth day, before the button separated, and was due to the administration of food. Though these buttons had sometimes dalled in the intestine and had gone up the canal instead of down it, yet on the whole their use would probably be followed by a better result than other methods. The operation lasted fifty minutes, but most of this time was spent in ligaturing the numerous cut vessels in the mesentery.

Dr. HECTOR MACKENZIE detailed the notes of a case of Hysterical Contracture of the Legs. The patient, a young woman, had first come under his care at the age of twenty for symptoms which suggested gastric ulcer. She was at that time much emaciated, and suffered from gastric pain and vomiting. Some time after this she had some disappointment, lost power in her legs, and took to her bed; the legs soon became contracted, and remained so. When she came under treatment a second time the legs had been contracted for two years. She was now twenty-three years of age. Her

emaciation was great; her weight was five stones. Under the deepest anaesthesia it was impossible to extend the legs on the thighs beyond a right angle; flexion could, however, be performed up to the normal limits. The flexor tendons were hard and rigid. The patient was depressed, and dwelt much on her troubles. There was marked anorexia. From the history, the mental and physical condition, and the character of the contracture, Dr. Mackenzie concluded that the case was hysterical in origin. It seemed likely, however, that structural changes in the flexor muscles had supervened, and it was at first doubtful whether it would be possible to straighten the legs without performing tenotomy. It was considered that the first thing to be done was to improve the general nutrition and to cure the morbid mental condition. The case was treated in the general ward of the hospital with massage and high feeding. Letters and the visits of friends were strictly forbidden. At the end of five weeks the patient had gained a stone in weight and was much more cheerful. She was soon made to get up and was encouraged to use her legs a little. The contracture gradually but surely gave way. At the end of nine weeks the legs were nearly straight, and the patient had gained two stones in weight. She was discharged at the end of thirteen weeks well able to walk, with her legs quite straight, her weight nearly three stones more than when she came in, and in a cheerful frame of mind. She had now for two years been perfectly well. Dr. Mackenzie said that although such cases were not very often seen in hospital practice it was possible they might be met with more commonly by general practitioners or in infirmaries. As they were generally considered incurable they were not very likely to be brought to a hospital. It was very satisfactory to know that in such a well-marked and long-standing case ordinary methods of treatment had proved sufficient to establish a complete cure.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL MEETING of this society was held on March 1st, the President, Dr. R. J. BANNING, being in the chair.

Mr. BALLANCE showed a woman aged fifty-six years on whom he had performed Cholecystotomy during an acute attack of gall-stone colic. Eighty-five gall-stones were removed, and the mucous membrane of the gall-bladder was found to be ulcerated. The gall-bladder was stitched to the skin and the patient made an uneventful recovery.—Mr. BIDWELL remarked that in most cases of cholecystotomy it was preferable to stitch the gall-bladder to the peritoneum and not to the skin.—Mr. BALLANCE also showed a boy aged fifteen years on whom he had operated for Cerebellar Abscess. The patient had suffered for nine years from otorrhoea and for five weeks from headache, staggering, vertigo, vomiting, and nystagmus. The temperature was subnormal. Operation was performed immediately after admission, and half an ounce of pus evacuated from the anterior part of the left lateral lobe of the cerebellum; blood-clot subsequently formed in the site of the abscess and caused a return of his symptoms, but on removal of this a complete recovery ensued.—Dr. ALDERSON remarked that the symptoms produced by cerebellar abscess were often quite indefinite and resembled those of typhoid fever or meningitis. He referred to a case which was diagnosed as typhoid fever, but at the post-mortem examination a cerebellar abscess was found.—Mr. MADDLOW, Dr. PEGHIER, Mr. ECCLES, and Mr. LAKE also took part in the discussion.

Dr. BUCKLAND showed a case of a young man suffering from Progressive Muscular Atrophy, which was improving under electrical treatment. The muscles of the forearm and front of the legs were alone affected.—Dr. EDDOWES suggested that the case might be syphilitic in origin.

Mr. EDWARDS showed two cases of Fracture of the Patella which he had wired four and six weeks ago respectively. He operated by a lateral flap and hammered in the ends of the wire. The splint was removed at the end of a fortnight. The movement of the joint was excellent in each case.—Mr. ECCLES noticed that in both these cases the injury was due to a fall on the knee, and stated that transverse fractures with separation of the fragments followed much more often than was formerly supposed.—Mr. EDWARDS also showed a boy with Epispadias affecting the Glans and a portion of the

Corpora Cavernosa. He regarded the condition as congenital, but suitable for operation.—He also showed a Ruptured Kidney which he had removed from a man aged fifty-five years who had fallen on a spiked iron railing. The kidney had been transfixed by the spike and was ruptured completely. It was removed by a lumbar incision, and the patient was doing well.—Mr. KNETLEY referred to a case of laceration of the kidney where he had removed the lower half of the organ; the bleeding was controlled by packing the wound with sponges, which were removed on the day after the operation.

Dr. BALL showed a man aged forty who was suffering from Bradycardia. He had been under observation since December, during which time his pulse-rate varied between 26 and 30 per minute. At times a systolic murmur could be heard. The patient had enjoyed good health until one year ago, when he had influenza; he used to drink rather freely.—Dr. CHAPMAN considered that there was fatty degeneration of the heart.—Mr. Maidlow, Dr. Weber, and Mr. Lloyd also made remarks.

Dr. ABRAHAM showed a patient with a Tertiary Syphilide which suggested a mixture of syphilis and eczema seborrhoeica. The itching was intense, and the eruption had an annular margin.—Messrs. Lloyd and Eccles discussed the case.

Dr. CHAPMAN showed a girl aged twelve years with Displacement of the Heart to a point three-quarters of an inch outside the right nipple. The right chest measured half an inch less than the left, and there was some spinal curvature. There was bronchial breathing on the right side. Dr. Chapman considered that the condition was the result of contraction of the lung from old fibroid disease.

Mr. KEETLEY showed a case of Primary Chancre of the Upper Lip in a girl aged eighteen. There were some enlarged glands, but no rash or sore-throat. The patient was improving under mercurial treatment.—Mr. KEETLEY also showed a woman aged fifty years who came under his care with Eczema of the Nipple and a Chronic Abscess in the Breast. The abscess was surrounded by cicatricial tissue, which resembled scirrhus; it was dissected out and the breast was now quite free from disease.

Mr. BIDWELL showed a girl aged nineteen suffering from Myxedema, together with considerable enlargement of the hands. The enlargement was apparently due to repeated attacks of erythematous inflammation. Symptoms of myxedema had existed for two years.

ÆSCULAPIAN SOCIETY OF LONDON.

The Action of Cardiac Tonics.—Diphtheria treated with Antitoxin.—Facial Paralysis.—Synopsis of 1000 Cases of Midwifery.

A MEETING of this society was held on Feb. 22nd, the President, Dr. A. G. BARTLEY, being in the chair.

Dr. A. K. CHRISTIE gave a brief summary of observations on the Action of Cardiac Tonics—namely: (1) digitalis, which caused a long systole by stimulating the cardiac muscular fibres, a long diastole by acting on the vagus, and vascular contraction by its effect on the vaso-motor centre—in spite of this triple action he considered it inferior to (2) strophanthus, which affected almost solely the cardiac muscle fibres, and was more persistent and more rapid in effect than digitalis; (3) convallaria, resembling strophanthus in action, and best given as an infusion, its most useful principle, convallamarin, being soluble in water, in which convallarin, a gastro-intestinal irritant, was insoluble; (4) caffeine, another of the same group as 2 and 3, was best used as a soluble salt (the sodio-salicylate)—its decided antagonism to morphia interfered very materially with its general utility. A series of sphygmograms illustrating this paper was shown at a former meeting of the society.

Mr. H. P. MILLER gave notes of a case of Diphtheria treated with Antitoxin in which Tracheotomy was performed. Three days after the disease was observed in the fauces the breathing became difficult, and on the fourth day 12 c.c. of antitoxin were injected. Next day tracheotomy was performed, and membrane was coughed up from below the opening. Later, 6 c.c. of antitoxin were injected, and next day (sixth day of disease) 6 c.c. more. The urine was albuminous. The tube was removed on the tenth day after operation. It was noted that this case, in spite of very insanitary surroundings, did exceptionally well and that the expectoration soon became fluid instead of membranous.

Mr. G. ELAM showed a case of Facial Paralysis apparently peripheral, and due to cold. There was no evidence of a central cause. Mercury with iodide of potassium, and electricity had been used, but with little or no effect.

Dr. J. W. HUNT gave a Synopsis of 1000 Cases of Midwifery. In these primiparæ numbered 289 (29 per cent.), arm presentations 4 per cent., breech ditto 2 per cent., and face, 3 per cent. The occiput was posterior to the last in 3.5 per cent. There were 4 cases of funis presentation, 1 of placenta prævia, and 1 of craniotomy. Post-partum hæmorrhage occurred in 6 cases. Forceps cases numbered 188. The head was high in 47, intermediate in 101, and low down in 40. The percentage of forceps cases was about 30 for primiparæ and 14 for multiparæ. Foetal deaths amounted to 6 per cent. Dr. Hunt advocated the use of forceps in all cases of delay, and usually gave ergot (about two drachms) as a preliminary.—Dr. CHRISTIE considered ergot to be a much overrated drug. He had given one ounce without exciting uterine contraction.

CAMBRIDGE MEDICAL SOCIETY.

Antitoxin Treatment of Diphtheria.—Laryngeal Growths.

A MEETING of this society was held on Feb. 1st, the President, Professor CLIFFORD ALLBUTT, M.D., F.R.S., being in the chair.

Dr. LATHAM, after giving a short history of the serum treatment of diphtheria and describing the method by which Behring's antitoxin is prepared and the way in which the strength of the preparation is determined previously to its use, reported five cases which had been treated under his directions by the remedy. Two of the cases presented points of special interest, tracheotomy having been performed, the membranous exudations extending into the trachea and bronchi, and both patients recovering. A number of microscopical specimens and cultures from each of the cases were shown by Dr. COBBETT, John Lucas Walker Student of Pathology in the University.

Mr. WHERBY showed a lad who had suffered from aphonia and stridor, his breathing being seriously affected. Dr. Laurence Humphry, under whose care the boy was in Addenbrooke's Hospital, had discovered papillary growths obscuring the greater part of the vocal chords, and advised their removal. Mr. Wherry performed preliminary tracheotomy, and after a few days opened the larynx by median section of the thyroid cartilage. He removed a large quantity of papillomatous growths from the interior of the larynx and also from the region of the false chords. The growths bulged into the incision as soon as the thyroid cartilage was cut, and they were cleared away by Löwenberg's forceps and by sponging. No after application was needed. The case did very well and both voice and breathing were unimpaired.

LIVERPOOL MEDICAL INSTITUTION.

Mycosis Fungoides.—Pneumonia with Relapse.—An Unrecognised Danger in the Administration of Chloroform.—Course and Treatment of Acute Rheumatic Endocarditis.

A MEETING of this society was held on Feb. 28th, Mr. CHAUNCEY PUZEY, President, being in the chair.

Dr. LEALIE ROBERTS read a paper on a case of Mycosis Fungoides. He pointed out that the symptoms in the early stage simulated eczema and other inflammatory eruptions, but were in reality neoplastic in nature. The tumours were infective, but there was no evidence at present of the action of micro-organisms. The necropsy showed the presence of tubercle bacilli in the left lung. The consideration of the histo-pathology of the disease was deferred to the pathological section of the society.

Dr. GLYNN related a case of Pneumonia with Relapse. He said that there was a great divergence of opinion as to the frequency with which relapse occurred, some authorities considering that a relapse was extremely rare, whilst others found it in from 15 to 25 per cent. of their cases. A man was admitted into the Royal Infirmary who had been ill three days; he convalesced on the tenth day, and remained well for eleven days; he then had a distinct relapse. The pneumonia was at both bases of the lungs. A very favourable point in the case was that the respiration never rose above 30 per minute; this showed that the rapidity of the breathing did

not depend altogether on the physical condition of the lungs, but probably on the presence of toxines circulating in the blood and affecting the respiratory centre. The first sign of improvement (which occurred a few days before the temperature dropped) was an increase in the quantity of urine secreted; Dr. Glynn considered that this was a most important sign of recovery. The case was treated by two drachms of infusion of digitalis given every two hours. Dr. Glynn considered this a most valuable remedy in pneumonia, and said that it would produce sleep and quiet the patient when other drugs failed to do so. It was stated, however, that cases treated with digitalis were liable to relapse.

Mr. C. G. LEE read a short paper descriptive of the Spasmodic Cough and Laryngeal Irritation that often occurs to the operator and his assistants when Chloroform is administered in an ill-ventilated room in proximity to a gas flame. The only record of such cases that he had been able to discover was to be found in a paper published in vol. xiii. of the *Practitioner* by Dr. Paterson of Cardiff. Here, however, the patient, as well as the surgeon, suffered from the violent cough and irritation, rendering it dangerous to proceed with the operation. In none of Mr. Lee's cases had the patient suffered. The exact nature of the irritating substance was discussed, and Dr. Paterson's view that it was probably carbon oxychloride or phosgene gas was favourably commented on; at the same time it might be due to free hydrochloric acid, as suggested by Dr. Carter. Several speakers pointed out that the same symptoms of irritation occurred when ether was administered in the neighbourhood of a coal-gas flame.

Dr. CATON read a paper on the Course and Treatment of Acute Rheumatic Endocarditis. Whilst treating 300 cases of acute and subacute rheumatism during the last thirteen years, he had observed the occurrence of 51 cases of valvular disease of the heart. The early signs of cardiac complications were described, and also the means employed to prevent them. Thirteen of the cases received no special treatment beyond that appropriate to the rheumatism and were kept in hospital on an average for twenty-five days. Of these, 12 left the hospital with a bruit and 1 without. Thirty-eight cases were treated by repeated blistering over the cardiac region and by the administration of potassium iodide. Treatment was continued for an average of forty-one days. Of this latter number 28 left the hospital without any bruit and 10 with a bruit.—Drs. Glynn, Barr, P. Davidson, and Logan discussed Dr. Caton's paper.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Gall-stones successfully removed by Cholecystotomy.—Encysted Empyema.—Tuberculous Abscesses of the Liver.—Lymphoma of Eyelids.

A MEETING of this society was held on Feb. 15th, Mr. MAKEIG JONES being in the chair.

Dr. HELLIER showed eight Gall-stones successfully removed from a woman by Cholecystotomy. The case was interesting because there was present the condition which Riedel has described under the term "linguiform appendage of the liver." Before operation a movable solid tumour near the umbilicus had presented a diagnostic riddle which was only solved by exploratory incision.

Dr. CHURTON showed a case of Encysted Empyema on the Internal Surface of the Right Lung. The patient, a boy aged four years, in November, 1894, had diarrhoea for a fortnight; he then began to cough. On Jan. 5th, 1895, the usual signs of fluid were found in his right chest; he came into the Leeds Infirmary a week later; ten ounces of pus were obtained by incision. No improvement followed. On Jan. 29th the morning temperature was 100° F., evening 100° 6'; pulse, 144; respiration, 40. There was no dulness over the right lung except near the heart (supposed to be the margin of unexpanded lung adherent to the chest wall); no breath sounds in it. Bronchial râles were heard in both lobes of the left lung; variable dulness at base in axilla; the presence of fluid was doubtful; on exploration none was found. The heart was in the normal site, with perfectly normal sounds. There were signs of pericarditis with effusion. At the necropsy, four days later, upon removal of the sternum pus flowed from an accidental incision in what at first seemed to be the pericardium, but this membrane was found

to be perfectly healthy internally; externally it formed part of the sac of an empyema containing about an ounce and a half of pus, the opposite wall being the inner face of the right lung. The base of the lung was rather strongly adherent to the diaphragm. In the left lung there was bronchitis with a few red pneumonic patches, and there was a layer of semi-purulent exudation on the lower part of both lobes (outer aspect). Suppurative peritonitis (recent) and caseous mesenteric glands were also found. The superficial dulness presented by the internal empyema during life did not much exceed half an inch; the coexisting diseases in the abdomen and opposite lung prevented this sign from receiving sufficient attention. The cavity of the external empyema was smooth and contracting.

Dr. CHURTON showed a Liver in which there were Abscesses of various sizes, from a pea to a small orange. The large cavities contained pus, with shreds and bands of necrosing tissue. The patient, a woman aged thirty-six, had had a cough for two years, with little expectoration. During the last six months she had passed several gall-stones, with pain and transient jaundice; the last attack occurred two months before death. During life the liver was somewhat enlarged and the edge rounded; there had been no jaundice recently. Tuberculous fibrosis was found in the upper lobes of the lungs, and miliary tubercles in the lower lobes. There were no intestinal ulcers; three or four small, hard, calcareous glands were found in the mesentery. The gall cyst was small; there were no calculi. Mr. Stott, pathological curator, found tubercle bacilli in pus from the liver.

Dr. ADOLPH BRONNER showed a microscopic specimen of Lymphoma of the Eyelid. Seven years ago an oblong elastic growth ($1\frac{1}{2}$ in. by $\frac{1}{2}$ in.) was removed from the left lower eyelid. There was no recurrence for three years; then all four eyelids, right hard palate, and right sub-maxillary gland became affected. The internal use of arsenic reduced the growths, but as soon as the arsenic was discontinued they increased in size. Slightly similar cases had been recorded by Goldzieher, but these were lymphadenomata and unilateral. The case, with photograph, was described in the Transactions of the Eighth International Ophthalmological Congress.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Chronic Stricture of the Urethra.

A MEETING of this society was held on Feb. 14th, Mr. RICHARD FAVELL, Vice-President, being in the chair.

Mr. ATKIN showed a girl from whom he had removed the Shaft of the Ulna for Necrosis without Suppuration.

Mr. PYE-SMITH showed three boys on whom he had recently performed Excision of the Hip by Anterior Incision, and advocated this operation as giving better results than that of external incision.

Dr. MARTIN showed: (1) an Ovarian Cyst and Cystic Ovary from a patient twenty-four years of age; (2) an Ovarian Cyst with a Twisted Pedicle from a patient thirty-four years of age; and (3) a large Fibroid measuring $12\frac{1}{2}$ in. by $11\frac{1}{2}$ in., which he had removed from the vagina of a patient aged fifty. All the patients made good recoveries.

Mr. KILHAM read notes of: (1) Accidental Vaccination by bathing a small wound on the cheek of a boy three years of age with a sponge which had just been used to wash the arm of an infant vaccinated on the previous day; (2) unusually large Child stillborn; weight $17\frac{1}{2}$ lb., length 25 in., and with the arms to the sides 11 in. across the shoulders; and (3) a curious Bicycle Accident, causing Rupture of the Urethra without any skin wound.

Mr. W. H. BROWN (Leeds) read a paper on Some Points in the Treatment of Chronic Stricture of the Urethra. In the presence of cystitis in at all a severe form or with an abnormally sensitive urethra he considered the treatment by dilatation, either rapid or gradual, decidedly dangerous. Internal urethrotomy he condemned, but external urethrotomy on the lines laid down by Mr. Wheelhouse he regarded as a safe and efficient method of dealing with chronic stricture. One advantage of this operation was that it afforded the operator an opportunity of exploring the bladder, which in one of his own cases led to the discovery of two unsuspected

calculi. It also provided for efficient drainage of the bladder subsequently, which no other plan of treatment did. Mr. Brown said that he always varied Mr. Wheelhouse's method of procedure by the insertion of a perineal tube into the bladder, allowing it to remain there for four or five days; and in bad cases he washed the bladder out with solution of quinine. With regard to the risk of serious hæmorrhage, which had been alleged as an objection to this operation, he said he had only once met with any trouble from this cause, and he had never known suppression of urine to follow external urethrotomy, as had been the case after dilatation several times in his experience. In conclusion, he strongly deprecated undertaking such an operation as external urethrotomy without at least three assistants—in fact, with as many assistants as would be present if the operation were performed in a hospital.—The Vice-President, Dr. Keeling, Mr. Pye-Smith, Dr. Sinclair White, Mr. Atkin, and Mr. Snell joined in the discussion which followed.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

The Adjourned Discussion on Cardiac Therapeutics.

THE adjourned meeting of this society for the conclusion of the discussion of Cardiac Therapeutics was held on Feb. 26th, Dr. CLOUSTON, President, being in the chair.

Dr. G. A. GIBSON wished to speak of the relief of cardiac pain, which was a subject of the highest importance, especially in the senile heart. He could draw no hard line between the different forms of cardiac pain. The pain was a central discharging lesion. It was usually connected with some area of hyperæsthesia. The pain of "impending sense of dissolution" was not specially cardiac, but seen in ovarian and other abdominal lesions. He agreed with Dr. Balfour when he said there was no angina without cardiac failure of some sort. The vaso-motor form would not hold water. To relieve the pain the nutrition of the circulation and primarily that of the heart must be improved. As drugs we must give the first place to the iodides, especially iodide of potassium. Iodide of ethyl was considerably more active, less evanescent in its action, and more certain than nitrite of amyl. The nitrites were more useful in asthmatic than cardiac conditions. Of other drugs, opium was a sheet-anchor in painful conditions in old people, and if used with ordinary precautions there was really no risk. The diathesis of the patient must be considered. In gouty people alkalies and colchicum were of use. Cardiac pain signified cardiac failure. He doubted if anemia of the cardiac muscle could produce them, or neuralgia, or neuritis. Probably they were due to local irritation of sensory nerves. He dwelt on the usefulness of distilled water as a drink in senile cases.

Dr. ALEXANDER JAMES expressed some doubts which he had in the treatment of cardiac cases. Were we really husbanding the strength of the heart when we reduced its rate and increased the blood pressure with drugs? Did we not give the heart more work to do? Did our fathers not rather husband the strength of the heart in the early stages of the disease by lowering the blood pressure by means of antimony, venesection, &c. Again, could we not do more good by getting the patient to sleep instead of giving tonics? During sleep the heart got slower.

Dr. GEORGE BALFOUR desired to make some supplementary remarks on the present question, rather than discuss the merits of certain drugs. Exercise he thought only applicable in the early stage of gouty heart. Excessive exertion tended to promote irremediable failure of the heart. In young people especially the nutrition of the skeletal muscles could be promoted by massage. He next glanced at the diet of a cardiac case, which he regarded as of very great importance. Of the drugs employed in cardiac cases nuxvomica was of value in all cases where the cardiac energy was defective, and could be continued for a long time. Five minims of the liquor strychninæ every twelve hours were a dose which did not produce cumulative effects, but marked and steady improvement due to the energising of the heart muscle, the cardiac ganglia, as well as the vaso-motor centre. Arsenic was also a valuable tonic; though it was difficult to understand how it acted there could be no doubt as to the benefit resulting. Of all cardiac tonics, digitalis was paramount. It was an indigenous drug of the highest value, which

gave its name to a whole group of remedies of similar action, of which only one came within measurable distance in the possession of valuable qualities—namely, strophanthus. The active principle of strophanthus was soluble, it acted with great rapidity, and so might occasionally be used with advantage in cases of cardiac collapse. The defect of strophanthus was that though it forced the heart to contract it had no tonic action on it, and did not promote the nutrition, which digitalis did. This was a special disadvantage in cases of senile heart. Digitalis produced the desired action on the heart with certainty and without risk. Digitalis might be given—(1) to improve the nutrition of the myocardium and so augment the force of its contractions; (2) to contract dilated ventricles; and (3) to remove dropsy. In using it as a tonic saturation must be avoided; thus a grain of powdered leaves or the equivalent might be given in twenty-four hours. This might be continued for months or years. In flabby or dilated heart larger doses might be used to contract the organ. In aortic disease where the ventricle was beginning to fail large doses at considerable intervals were required. For removal of dropsy a degree of saturation was required. When blood pressure was high purgatives were of the greatest use. In lowering blood pressure for a lengthened period without bad effect iodide of potassium was best, and was most useful in combination with digitalis. Referring to the statement that there was not always high blood pressure in angina, Dr. Balfour said he had at one time held that view, but he was now satisfied that there was always an initial rise, though it rapidly fell from the failure of the heart to keep the pressure up. In conclusion he glanced at the use of narcotics in cardiac cases.

Professor FRASER, replying, said that it had not been his intention in the remarks with which he opened the discussion to specially emphasise the merits of any one remedy, but to demonstrate the remarkable therapeutic value of a pharmacological group, which he illustrated in connexion with one member because his experience with it had been greater than with any other member. This group of remedies had a direct action on the muscle of the heart, increasing the strength and efficiency of the contractions with a power unequalled by any other remedies. Time alone had prevented him making more than incidental mention of secondary remedies, such as rest, diet, arsenic, nitrites, morphia, strychnine, measures for removing fluids and increasing elimination, &c. In conclusion, Professor Fraser, after ably and impartially reviewing the expressions of opinion of those who had joined in the debate, expressed his great gratification at the amount of interest the discussion of this important question had raised.

Reviews and Notices of Books.

Meteorology: Practical and Applied. BY JOHN WILLIAM MOORE, B.A., M.D., F.R.C.P. (Irel). London: F. J. Rebman. 1894.

DR. MOORE was so recently before the profession as the author of an important work on Fevers that it is something of a surprise to find him so soon again in the field with a volume upon Meteorology. But, as he informs us in his preface and as is well known, he has long taken an interest in questions of weather and climate, and these subjects have afforded him "the needful foil to his more serious professional studies and pursuits." Hence he enters this new field not as a mere amateur, but "has been able to bring no small practical experience of meteorology to bear in the writing of the following pages." Dr. Moore holds, and we think with justice, that the practical physician, although subject to numerous distractions which impede the systematic pursuit of pure scientific work, has many advantages in approaching the problems of climatology. "The physician, of all men, has the fullest opportunities of observing the far-reaching influence of weather and climate upon human health, happiness, and longevity." Our readers do not need to be reminded that a careful study of the weather and seasons, and the doctrine of "epidemic constitutions" founded on this study were

cardinal features in the system of Hippocrates. The present work has not much pretention to originality of fact or theory; but may be taken as a full, lucid, and satisfactory exposition of the present state of knowledge regarding the subject of which it treats. Dr. Moore does not presuppose much knowledge on the part of his readers and does not disdain to enter into minute details on the elementary laws of physics, the different kinds of thermometer, the history and principles of the barometer, and such like. Many of such details would, perhaps, be more proper to a school manual on physical geography than to a formal work on meteorology addressed to the medical profession; but, on the other hand, there is something to be said for the author making his ground secure as he goes along. We think it was Faraday who was once asked to explain the wonderful success of his popular lectures at the Royal Institution, and, in particular, how he was able to assume the amount of knowledge possessed by his auditors. His reply was that "the only safe course was to assume that they knew nothing." Dr. Moore acts upon this principle and does not credit his readers with even an elementary knowledge of meteorology. After a general account of the scope and aim of meteorology and the properties and composition of the atmosphere, the author proceeds to give a very full account of the various methods of practical weather observation adopted at the chief British and American meteorological stations. There is much in this part of the work that is interesting, and the facts will be new to many readers; but it is with some sense of disproportion that we find forty-five pages in a work of a little over 400 pages devoted to a minute description of the history, organisation, and work of the United States Weather Bureau. To take one instance of what seems to us superfluous material, the English reader can hardly be expected to take a deep interest in the number of books and pamphlets added to the library of the Washington Weather Bureau from its foundation down to 1893. Yet these facts are set forth in fullest detail, and we are further informed: "In addition to these various sections of the Bureau there is a large mass of correspondence to be cared for. This comes under the direct cognisance of the chief clerk, who has a small staff of clerks under him to perform this work. The letters received are assigned to the various divisions or individuals most competent to answer them. The replies are drawn up by these divisions or individuals with the aid of stenographers &c." Padding of this kind might profitably disappear from a second edition. We cannot leave this part of the work without expressing our admiration for the thoroughness with which the task of recording meteorological phenomena is discharged by our contemporaries in America. They have special advantages for the organisation of a complete and efficient national system of weather observation, and it is only just to acknowledge that these advantages have been utilised in a highly satisfactory and creditable manner.

After a full exposition of the general facts relating to such subjects as atmospheric pressure, the aqueous vapour of the atmosphere, winds and wind gauges, and atmospheric electricity, Dr. Moore proceeds in Part III. of his work to consider some of the general problems of climate and in more detail the climate of the British Islands. The factors of climate are stated to be the following: latitude, altitude, relative distribution of land and water, presence of ocean currents, proximity of mountain ranges, soil, vegetation, rainfall, and prevailing winds. The author's description of the winter climate of the British Islands is worth quoting. "During the earlier winter months a great stream of warm, very moist air, as a rule, flows north-eastward and northward over these islands round the Atlantic depression, the centre of which lies near Iceland. But this stream does not flow evenly. Along its eastern edge it is in continual conflict with the cold anticyclonic air which is travelling westward

from Russia and Siberia, and immense volumes of the latter are frequently rushing in to supply the place of those volumes of the warm air which, owing to their low density, have presumably risen from the earth's surface towards the higher strata of the atmosphere. This conflict between two such opposite currents of air causes our storms and those violent and rapid alternations of temperature which are so prejudicial to health in the winter months."

The fourth and concluding portion of Dr. Moore's work is devoted to the influence of season and weather on disease. No attempt is made to deal exhaustively with this large subject, but the leading facts are marshalled in a clear and interesting way. The chief points emphasised are that influenza is absolutely independent of season and weather, that cholera tends to prevail in the warmer months of the year, that diarrhoeal diseases belong to summer and autumn, that enteric fever is most prevalent in autumn and early winter, that typhus fever is a disease of winter and spring, small-pox belongs also to these seasons, that measles is most prevalent in the spring and autumnal quarters of the year, and that scarlet fever, though little dependent on climatic causes, tends to increase in the fourth quarter of the year. As regards pneumonia Dr. Moore draws a distinction between ordinary pneumonia and "pythogenic" pneumonia, the former being specially prevalent during a continuance of cold, dry weather, with high winds and extreme variations of temperature, while the latter reaches its maximum during tolerably warm weather, accompanied with a dry air, deficient rainfall, hot sun, and rapid evaporation. With this disease the writer ends, though it cannot be said that the subject was worked out; but he would be the first to disclaim completeness for a work which proceeds, on the whole, upon elementary lines. We may say, in conclusion, that the work is well printed and handsomely illustrated.

Transactions of the Pathological Society of London. Vol. XLV. London: Smith, Elder, and Co. 1895.

ALTHOUGH less bulky than many of the preceding volumes of these invaluable Transactions—which form a rich storehouse of pathological facts that has been often drawn upon by authors in all parts of the world,—nevertheless, the forty-fifth volume contains many valuable contributions to knowledge. Dr. Tooth records the results of his examination of the nerve trunks in a case of alcoholic paralysis, important from the examination having been made in an early stage of the disease and from the lesions being degenerative rather than inflammatory. Dr. Semon and Mr. Shattock record the sequel to a case of "anomalous tumour of the larynx," first brought forward three years previously. The interest of the case lies in the growth being proved to be of malignant nature, although clinically the case did not run the course of malignant disease. The somewhat rare condition of diphtheria of the stomach is described by Dr. W. S. Fenwick, the case lacking, however, a bacteriological examination and being remarkable from the freedom of the pharynx and œsophagus from exudation. Two cases of general ulcerative colitis by Dr. Tooth are illustrated by excellent photographs, recalling those in the late Dr. J. J. Woodward's memoirs on the intestinal affections observed in the American War of the Rebellion. Dr. Newton Pitt shows how aberrant renal vessels may cause hydronephrosis; and Mr. Shattock describes some new facts in the anatomy of epispadias and extroversio vesicæ. Some specimens of bone disease described by Mr. Clutton (syphilitic osteitis) and Mr. Davies-Colley (syphilitic disease of the knee-joint) are admirably shown in photographs; indeed, almost all of the plates are of the photo-lithographic order. There are several contributions to the subject of Rodent Ulcer, notably an analysis of sixty-six cases by Mr. Bowlby and a detailed histological report by Mr. F. T. Paul. The

subject of mammary carcinoma is studied by Mr. Cecil F. Beadles; but the question of sporozoa and cancer, which barely a year since was a burning one, seems to have received but scant attention during the last session of the society.

MAGAZINES FOR MARCH.

Westminster Review.—The current monthly number contains several articles of considerable interest and is not quite so strictly instructive without being recreative as usual. In the annals of the Modern Novel we have a decidedly bright and entertaining article and one that has a distinct interest for all medical men. It is no use blinking the fact that the majority of our better-class patients nowadays depend on their fiction for much of their knowledge and most of their estimates of personal theories and things, so that it is not an unusual thing for the medical man to find himself face to face with a case where many of the symptoms and possibly many of the evil practices that have determined the symptoms or the condition are directly or indirectly dependent upon the patient's taste in fiction. Mr. Hannigan's very short paper advocates chiefly the abolition of the controversial novel, and winds up with the dictum that Mr. Thomas Hardy is the only English novelist who never forgets his true vocation "to write a natural story of human life." Now, although Mr. Thomas Hardy displays none of the repulsive realism of Zola or Sereno and is free from the nastiness of what may be termed "the yellow school," he has more than once introduced episodes into his books which cannot have been calculated to do the greatest good to the greatest number by giving them the healthiest pleasure. We do not enter into the wider question of whether this is the legitimate aim of fiction, rather than what Mr. Hannigan considers the novelist's vocation; we speak only for medical men when we say that the tyranny of the modern novel is certainly excessive, and that Mr. Thomas Hardy is not the most pleasing exponent of English manners. In the same magazine there is an able defence of modern private asylums, which in view of the serious charges about to be investigated at one of the best known of these institutions, and in view also of the sensational recrudescence of attacks upon institutions for the insane, makes very appropriate reading.

The *Contemporary Review* contains a paper of particular interest to us all in a quasi-defence of the late County Council in respect to the music-halls from the well-instructed and vigorous pen of Mr. William Archer. It would appear from a careful study of the results of the County Council election that the Moderate party do not owe their success to any popular resentment of the action of the Council in the Empire case, and so far it would seem that the "shriek of indignation and terror" which "went up to high heaven from a thousand journalistic throats" (Mr. Archer's expression) has had exceedingly little influence upon lower earth as represented by the London voter. But none the less the question of the position of municipal bodies as moral guides is a particularly interesting one at the present juncture.

The *English Illustrated Magazine* contains, amidst a wealth of short stories by popular authors, an interesting account of the foundation of Messrs. Bass's Brewery. The whole article is interesting from the popular point of view, and we wonder how many people believe that the water of the Trent plays an important part in the production of Burton ale. As a matter of fact, it is only used for washing the casks and similar purposes, while the water which is made into beer is drawn from wells varying from 20 to 130 feet in depth deriving their supply from the springs in the hills on the other side of the valley.

The *Pall Mall Magazine*, like the *English Illustrated*, is largely given over to fiction, and very well chosen and brightly written fiction too. But among the serious articles there is a paper by Mr. W. H. Mallock which we recommend

to the attention of our readers. Mr. Mallock is one of the few people who can write upon political economy and make the subject readable and even piquant, and students of his novels know this. In this article, cleverly adorned with illustrative diagrams, he makes clear the condition of the people in respect to the census in a very remarkable manner.

The *Humanitarian* has a short article from the pen of Mr. W. S. Caine, M.P., upon the Gothenburg Liquor System, which should go far to damp the ardour of enthusiasts for that system.

New Inventions.

"COMPACTUM" MIDWIFERY BAG.

THE above illustration shows a very portable midwifery bag, which has been brought before the notice of the profession by Messrs. Arnold and Sons of West Smithfield. It only measures 10 in. by 8½ in. by 3½ in., but nothing is lost in variety of contents by the limited size of the bag. It contains Barnes' long forceps, metal handle (folding), craniotomy forceps and perforator to fit into the same handle, blunt hook and crotchet (jointed), frenum scissors, and female catheter. All the instruments are nickel plated, and fit in the base of the bag. The left side holds one bottle each of Messrs. Burroughs and Wellcome's tabloids in a morocco leather

case, containing the following drugs: ergotine (3 gr.), anti-pyrin (5 gr.), chloral hydrate (5 gr.), Warburg's tincture (30 m.), opium (½ gr.), ammon. carbonate (3 gr.), hydrarg. perchloridum (solids, one solid in one pint of water, 1 in 1000), and potassii permanganas (solids, 5 gr.). The right side contains a morocco leather hypodermic case, with silver-plated syringe, two needles, and one tube of each of the following tabloids: atropine (½ gr.), caffeine sodio-salicylate (½ gr.), cocaine hydrochlorate (½ gr.), digitalin crystalline (½ gr.), ergotinlin citrate (½ gr.), pilocarpine hydrochlorate (½ gr.), strychnine sulphate (½ gr.), eserine salicylate (½ gr.), hyoscyne hydrobromate (½ gr.), morphine sulphate (½ gr.), morphine sulphate (½ gr.), atropine sulphate (½ gr.), sclerotinic acid (½ gr.), one collapsible tube of lano-creolin, one collapsible tube of hazeline cream, and one capped, stoppered bottle for chloroform. The price of the bag, complete with instruments, drugs, &c., is £6 15s.

PILL BOX SHOOT.

THE illustration shows a very handy and cleanly way of keeping pill boxes for immediate use. The appliance hangs on the wall, where it takes up very little room, the size being 37 in. long by 7 in. wide, and it projects only two inches. It holds three dozen one-ounce boxes, four dozen half-ounce, four dozen two-drachm, five dozen one-drachm, and six dozen half-drachm; and it is impossible for the practitioner to run out of stock without warning. The saving of time and temper thus ensured warrants us in thinking that this little apparatus will be well thought of in every pharmacy, surgery, and dispensary. The price is 10s. 6d., and the makers are Messrs. Reynolds and Branson, 13, Briggate, Leeds.

THE LANCET.

LONDON: SATURDAY, MARCH 9, 1895.

IT must at once be gratefully acknowledged that Mr. ASQUITH'S Factory Bill is a very satisfactory measure. Reforms on which for years we have insisted are here accorded, so far, of course, as factory legislation is concerned. It is, indeed, difficult to find fault with the proposals laid before the House. The most that can be said is that they perhaps need here and there a little strengthening and elaboration. The Bill has truly been defined as being framed in the spirit which animated the whole of our factory legislation; the difficulties in the past have arisen from the difference between the spirit and the letter of the law. We trust that the Bill now under discussion will prevent such constant misinterpretation of the spirit of the law. Thus, as Mr. ASQUITH very truly pointed out, overcrowding is illegal, but, as overcrowding has never been defined, of course the law could not be effectively applied. Now it is proposed to define overcrowding as less than a minimum of 250 cubic feet of space for every person in a factory or workshop, and 400 feet when overtime is worked. This minimum is further to be increased when artificial light is employed. This will not only help to improve sanitary conditions, but it will tend to lessen the abuse of overtime. Of course, these stipulations do not solve the question of overcrowding in so far as it depends on ventilation. Naturally, where the ventilation is scientifically managed, the amount of space required per person for the preservation of health need not be so high. This is well illustrated in the case of theatres; for instance, the ordinary London theatre does not compare well with the Vienna Opera House, which is one of the European models of good ventilation. No Bill, however, could prescribe measures of ventilation, and it was much easier to decide that there should be no overcrowding.

With regard to the prevention of accidents, "young persons" as well as children are not to be allowed to clean machinery in motion, and in new factories more space is to be provided between the various machines. We have been in mills where we had to take the utmost care not to be caught in the machinery, so narrow was the space which formed the passages. Then there is to be better provision against fire, and against defective or dangerous machinery, a court of summary jurisdiction being empowered to require that such machines shall not be used. Occupiers of factories or workshops will have to keep a register of all accidents that occur for the inspectors or the certifying surgeons to view, and the Secretary of State will be able to direct that inquiries shall be made. Thus what is done now when accidents happen in coal mines will be done when accidents occur in other occupations, and it should also be noted that a Bill has been introduced by the Lord Advocate, Sir GEORGE TREVELYAN, and the Solicitor-General for Scotland to make provision for public inquiry in regard to

fatal accidents occurring in industrial employment or occupations in Scotland.

With regard to the important question of "sweating," Mr. ASQUITH pointed out that it was not practicable to make the giver-out of work responsible for the sanitary condition of the place where the work was done. The work was sometimes given out in London and done in Scotland. It is proposed that factory inspectors, having ascertained that outwork is being done under unwholesome conditions, shall give notice to the employer and prosecute him if a month after the notice is served the work is still given out. Such measures are to be taken "where the evil is supposed to exist and in certain areas to be prescribed." This sentence is really mischievous, for it suggests that action is only to be taken in certain localities and under certain circumstances; but the evil is widespread. It may be intensified in some localities; it exists everywhere. Undoubtedly there are more sweating dens in the East-end than in the West-end of London, but there are a large number of sweating dens in the best quarters of the town. There is no need to pick out a special area; there are overcrowded insanitary workshops all over England. A list of every place where work is done should be kept and such places subjected to inspection. If it is not practicable to make the giver-out of work responsible for the sanitary condition of the place where his work is done, he must in any case supply the inspectors with the addresses and let them see to the sanitary conditions; and this should be obligatory all round in every trade and in every district. Nor would such control apply only to sanitary conditions, but also to the question of the hours of labour for women, children, and young persons. In the matter of overtime a great deal too much latitude has been allowed. Why should cigar makers, envelope folders, and such persons be allowed to work overtime? That overtime should be worked to preserve perishable articles—fruit, fish, and the harvest—is to the advantage of mankind; but need young women be kept toiling through the night because some fashionable lady wants to go to a ball in a new dress? It is quite right to pay respect to the dead, but many delicate, under-paid, and under-fed women have been brought early to the grave through the constant overstrain arising from the hurried execution of orders for suits of mourning. Fortunately the grievance of overtime will be to some extent mitigated by Mr. ASQUITH'S Bill, for he proposes to reduce the overtime allowed from forty-eight to thirty-eight days per annum and from five to three days per week, and for perishable articles from ninety days to sixty days per annum. It is to be hoped that, though Mr. ASQUITH was not ready to risk the fate of the Government on the subject, the House will assent to raising the minimum age for the employment of children from eleven to twelve years, and thus place us in accord with the Berlin Conference on Labour, where the representatives of the British Government assented to this proposal.

In dealing with laundries Mr. ASQUITH has repeated all that we have said in these columns as to their insanitary and unsafe condition, and he proposed to bring them all under the Factory Act. "The Act should apply," he said, "only to laundries carried on by way of trade, and not to laundries where the persons employed were members of the same family." We trust we do not misunderstand

this sentence. It should mean that, while persons may do their own washing in their own house without interference, they must not take in other people's washing. In the latter case washing is a trade and the Factory Act should apply. As for persons employed being members of the same family this is a very unfortunate sentence. It might mean that a family may not wash their own linen at home if they employ their own private domestic servant to aid in the work. If, as we very much fear, it is meant that persons may wash for others so long as they do not employ hired assistants the law will be constantly evaded. In sweating dens girls found there after hours are frequently represented as members of the family who have come up from the country to see the sights of town; and in the face of their employers they dare not deny these falsehoods. Besides, evil sanitary conditions are not made any better because the workers are all of the same family.

Mr. ASQUITH also includes bakehouses in his Bill. Those bakehouses that at present escape from the law because they existed before 1883, or are in towns of less than 5000 inhabitants, will now be included, and no exception will be made. There are also excellent clauses by which it is proposed that the temperature in workshops and factories where clothing is made should be kept up to 60° F.—a rule which might with advantage be extended to many other trades—that every workshop must be registered, and that docks, harbours, and the construction of buildings shall be brought, for the first time, under the scope of the law. We cannot, for the moment, do more than thus briefly scan the main provisions of the proposed measure. That it is a good Bill—we may say the best Bill that has been introduced in the House on the subject—will be very generally admitted. Still, as we have pointed out, there are one or two clauses that must be more fully explained, notably with regard to home washing and to the giving out of work. This, doubtless, will be made more clear in the course of the discussion on the future stages of the Bill, and we trust this project may soon become the law of the land.

A VERY interesting and important paper on "Thyroid Feeding in Insanity," by Dr. LEWIS C. BRUCE, of the Royal Edinburgh Asylum, Morningside, appears in the last number of the *Journal of Mental Science*. Dr. BRUCE says that he was first led to try the effect of thyroid feeding on the insane by noting that in various cases of myxœdema described as treated in this way the temperature rose from subnormal to normal and even became feverish, while the pulse-rate also was quickened. Bearing in mind the low temperatures and slow pulses often noticed among the insane, it appeared feasible that if one could induce quickened pulse-rates and higher temperatures there might be corresponding mental or physical improvement. Two cases of extreme mental deterioration were selected as trial cases, and the administration of thyroid to those produced such an effect that a trial of the treatment on a much more extensive scale was adopted. The method of observation employed was both elaborate and scientific. A careful record of the condition of the various organs and of the pulse, temperature, &c. was made before the treatment

was commenced, and the record was continued during treatment. The drug in most cases was administered until a feverish condition was induced for two or three days, and it was considered that when the pulse became rapid, soft, and compressible the limit of safety was reached. Mental and physical changes were recorded on the chart from day to day. The following is a brief *résumé* of the various effects on the different systems. In the circulatory system there was among the symptoms at times a tendency to faint when the patient was in an upright position. One patient did actually faint. The pulse changes were the first indication of the effect of the drug. These were increased rate, increased volume, and lessened tension. Later, irregularity, intermission, and compressibility were induced, and the time it took the pulse to become normal after cessation of the treatment varied very much. In regard to the respiratory system, the rate of respiration was increased proportionately to the pulse-rate. One curious phenomenon was noticed—viz., that among five patients who had traces of dormant phthisis symptoms and signs pointing to a lighting up of the activity of the disease were induced by the administration of thyroid. The tongue usually became furred, the appetite diminished, thirst usually increased if the temperature rose, and nausea and vomiting occurred in several cases. In regard to the condition of the blood, in eight cases in which thyroid was the only drug administered, there was a reduction in the numbers of the red corpuscles and in the amount of the hæmoglobin, in all except one. The other seven cases took Bland's pills or a solution of citrate of iron and ammonia as well as the thyroid. In two of these there was a gain of hæmoglobin, in three a loss. Four gained in corpuscular richness, two showed a loss, and one neither gained nor lost. It thus seems, as Dr. BRUCE points out, that the effect which the administration of thyroid has in impoverishing the blood can be, in some measure at least, prevented by the simultaneous administration of iron. Integumentary changes were also observed during the treatment. The skin became moist and at times the perspiration was profuse. Flushings were also frequently present, the pigmentation of the skin was diminished, and the complexion became soft and delicate looking. Desquamation occurred to a greater or less degree in every case after the treatment was stopped. A careful examination and estimation of the amount of urine showed that thyroid produced no diuretic action, at least in the large doses in which it was given. This may be accounted for by the profuse diaphoresis which was produced. As regards nervous symptoms, no sensory disturbances were observed, nor were organic reflexes altered in the great majority of cases. In many instances the voluntary muscles showed symptoms of over-action, and fine tremors were present in the tongue, lips, facial muscles, and limbs. Headaches were frequently complained of, and the mental condition under treatment varied greatly. Some became depressed, some emotional and others irritable; while, on the other hand, the irritable, morose, and bad-tempered became placid and amiable. In some the improvement in the mental condition was noted while thyroid was being administered; in others this was only noticeable when the period of reaction was well advanced. All the patients slept well. The temperature seemed to vary

considerably according to external conditions. Twenty-three cases were treated, eight men and fifteen women: two men recovered, three were relieved, and three were not improved; of the fifteen women, thirteen recovered and two were not improved. Amongst the patients treated were cases of mania, melancholia, syphilitic insanity, puerperal insanity, lactational insanity, climacteric insanity, and general paralysis. From a careful perusal of Dr. BRUCE's paper it would seem that in thyroid extract we have a means of distinctly influencing certain cases of insanity. Even from the experience so far obtained by Dr. BRUCE he is able to furnish suggestions as to the kind of case in which it is likely to be beneficial, without effect, or harmful, and it may be that the future will furnish even clearer indications.

UNDER the heading of "Parliament and Prison Reform" we publish in another column a statement sent to us by a correspondent who attacks in unmistakable language the present administration of English local prisons. His allegations are of a serious nature, and we feel it to be our duty not to pass them over without observation, but rather in general terms to call the attention of the profession to the more prominent among them. The two main subjects of unfavourable criticism are the prevalence of insanity and the death-rate. The prevalence of insanity in English prisons is said to have doubled, and the death-rate is stated to be much higher than in Irish prisons, although there may be a semblance of its having decreased in English prisons. Our correspondent points out that prisoners committed in a moribund condition are not now sent to gaol, a fact which contributes to reduce the death-rate. Also it is now, he says, more generally the practice to release prisoners who are in a dying condition before the expiration of their term. 'All this naturally very materially contributes to reduce the death-rate, but it does not mean that the prisons are more healthy or that the system of management is more conducive to the preservation of life. On the contrary, since the centralisation and the more bureaucratic management of prisons we have had a rigorous assimilation of *régime*, which is certainly contrary to all physiological facts. It is preposterous to suppose that identically the same quantity and quality of food, clothing, and exercise will suit equally well an agricultural labourer and the weak, degenerate worker from a sweating den or an unwholesome and overcrowded slum of a big city. Formerly, when the prisons were under local management, there was a much greater elasticity in the rules applied, and there were modifications in diet and clothing to suit special local and individual conditions.'

No doubt the Prisons Act of 1877 was the means of shifting the responsibility for the management of prisons from the magistrates to the Central Prisons Board at the Home Office, and it would appear that it is to this centralisation of authority that our correspondent attributes all the evils of the existing prison administration to which he refers. Although his figures may appear in themselves to warrant the construction that he puts upon them, we are bound to say, in all candour, that we are not prepared to go the length that he does in condemning upon them alone the present management of our prisons. For instance, with

regard to the death-rate our correspondent says that "there must be something radically wrong in the management of English local prisons will be admitted when the death-rate is compared with that of the Irish prisons." To make this an effective argument against the present system it would be necessary to show, as a preliminary to the consideration of the question, that during the antecedent period of magisterial management the death-rate in English prisons was not higher than in Irish prisons, or, at any rate, that the difference was less marked. Another point that our correspondent does not appear to have given effect to in the conclusions at which he has arrived is that his allegations apply in all their seriousness to a body of individuals who did not change with the transfer of power from the magistracy to the Home Office—viz., to the medical officers of the prisons. The questions of mal-administration which our correspondent raises are essentially physiological and pathological, and we must say candidly that we have every reason to think that the medical officers of prisons accept the responsibilities placed upon their shoulders, and that, generally speaking, they endeavour to carry out their duties honestly and fearlessly. Very large discretionary powers are in the present, as they have been in the past, entrusted to prison medical officers in the matter of the health of the inmates of our gaols; and this is both unavoidable and a matter of necessity. If magistrates in old days altered diet, clothing, &c., it was on the recommendation of their medical officers; if a central authority, as alleged, does not modify diet, clothing, &c., it is because the medical officers do not recommend it. We feel bound to say this, for if it were not so our prison system would be an atrocity and a farce.

But a prison system has an existence not merely with regard to its internal life and administration. It must be regarded as having a wider scope and purpose in its relation to the reduction of the amount of crime and to the better safeguarding of life and property in our midst. It is abundantly clear that a penal system which tended to encourage individuals to go into prison rather than seek to earn a livelihood by honest labour is faulty and worse than useless; and, on the other hand, it must not be forgotten that many individuals find a *régime* in prison life which, apart from the loss of "liberty," compares favourably with the miseries which it is often the lot of wretched and unwholesome members of the community to undergo.

To whatever cause or causes the fact may be attributed it is surely most significant, and not altogether unhelpful as to results on the criminal classes, that the population of our local prisons has decreased since the passing of the Prisons Act in 1877 from 20,833 to 13,850 in 1894, the lowest point having been reached by a steady decrease in 1892, when the number was 12,663, and that, too, notwithstanding the increase in the general population. We agree with our correspondent in his outspoken statement as to the importance of the questions which he has raised, and we trust that these questions will be fully inquired into by the Prisons Committee now sitting. We shall look forward to their report with much interest, not to say anxiety, for we feel assured that they will deal with the complicated subject of prison administration, not only in so far as it concerns the

well-being of the inmates of our gaols, but also in its wider relations as an integral and most important part of the legislative effort to protect the community and secure the highest public good.

Annotations.

"Ne quid nimalis."

ANTITOXIN AS A PATENT MEDICINE.

A MATTER of great importance was raised on Monday evening last in the House of Commons by a question addressed by Dr. Farquharson to the President of the Board of Trade respecting the production of antitoxin serum. The question ran thus:—"Whether his attention had been called to the fact that a specification for the preparation by a German method of remedial substances, and in particular diphtheria antitoxin in a concentrated form, was accepted by the Patent Office on Jan. 26th; whether such patent would hamper the production of the serum in a concentrated form in this country for the use of public infectious and other hospitals and in the military and naval hospitals; and whether it was the intention of the Government to permit such a patent to be granted." Mr. Bryce replied to the effect that the application in question had been received at the Patent Office, and that, apart from opposition, a patent would be granted in due course; but he at the same time reminded his questioner that the Patent Act of 1883 contains provisions by which a patentee can, if necessary, be compelled to license the use of his process upon reasonable terms. The question of granting monopolies for such things as medicines is one which, as we have repeatedly pointed out, deserves to be considered quite apart from the general question of patents for inventions, the interest of the public in the subject matter being of so very special a character as it is. In the case referred to by Dr. Farquharson there is undoubted reason for a protest in the fact that the intending patentee is, we believe, a medical practitioner, who therefore is bound by the traditions of our profession to give freely to the public the benefit of his scientific discoveries or invention. It can be no reason for relaxing this rule that the medical man in question is not a British subject, for the ethical rule for which we have always contended is not of any merely local application. Even if it could be shown that the powers of the Board of Trade to control the exercise by a patentee of his monopoly were sufficient to secure the public against being prejudiced by the monopoly we should be in no wise reconciled thereby to the introduction of commercial methods into the practice of medicine. As in this matter we are convinced that we express not merely our own opinion but that of our professional brethren throughout the British Isles, we trust that our protest will be supported also by the public opinion of the profession in Germany.

THE PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS.

THERE is a singular resemblance between the circumstances attending the recent death of the President of the Royal College of Surgeons of England and those connected with the only other occasion in which the President of the College has died during his term of office. Mr. J. W. Hulka was to have delivered the Hunterian Oration on Feb. 14th, but was prevented from doing so by illness; on Feb. 19th he died. In 1831 the Hunterian Oration was delivered on the same day, Feb. 14th,

by Mr. (afterwards Sir Anthony White), and the chair was to have been taken by the President, Mr. Headington, but illness prevented him from being present, and Mr. Keate presided at the meeting. Within a very few days Mr. Headington's illness proved fatal. When an office like the presidency of the Royal College of Surgeons is held for only one or two years, it must happen but seldom that the holder of it dies; and, indeed, sixty-four years have elapsed since this contingency first occurred. The meeting above mentioned at the College of Surgeons on Feb. 14th, 1831, was remarkable as being one of the earliest attempts of the Members of the College to hold a meeting within the walls of the College. Half-an-hour before the delivery of the Hunterian Oration was announced to commence the Members present held a meeting, in which the chief subject of discussion was the recent exclusion of the surgeons of the Royal Navy from the levees of the king. When the chairman, Mr. Keate, entered, he suggested that the meeting should continue after the delivery of the Hunterian Oration, and this was done, and two resolutions were carried; the chairman had, however, laid aside his robes of office, and he announced that he was not acting in his official capacity. Nothing came of the attempt, and the Council declined to consider the resolutions, as the meeting was irregular.

MILK-BORNE INFECTIOUS DISEASE.

THE control of the milk traffic is a subject which is daily receiving more and more attention, both at the hands of the public and the profession, and we imagine that ere long the necessity of extending, and perhaps even of compelling, the execution of the powers possessed by sanitary authorities will have to be considered in a practical spirit. The subject is beset with difficulties, as attempts to saddle a specific industry with limitations and liabilities not inflicted upon other food-preparing industries would be naturally much resented; and it is certainly not in the interests of public health to render the conditions of any trade so irksome as to encourage the concealment of infectious disease—a result which the too rigid application in practice of the theoretical aspects of infection would be not unlikely to bring about. The establishment of creameries drawing their milk supplies from farms in the vicinity, and the mixing at the creamery of the several supplies obtained, has introduced into the milk trade a comparatively new source of danger. Obviously the mixture of infected milk with milk not infected is a step calculated to specifically contaminate the whole; and the risks thus incurred both to the consumers of the separated milk and even, perhaps, of the cream and its products, must be patent to all. In THE LANCET of April 21st and Nov. 10th of last year we published some interesting articles by Dr. J. J. Welply¹ of Bandon, Ireland, on the subject, in which he described an extensive outbreak of enteric fever due to the consumption of separated milk from a creamery, and indicated some of the restrictions necessary to prevent these occurrences. These articles, which have certainly added materially to our knowledge of the manner in which milk-borne disease may be spread, have now been reprinted from our columns and published in pamphlet form, and although Dr. Welply's remarks apply more particularly to Ireland, the laws relating to the milk trade in that part of the United Kingdom are so similar to those in force here, that his suggestions may be taken as applying with equal force to England. *Appropos* of milk-borne typhoid fever, we notice that Dr. P. Q. Karkeek, the medical officer of health of Torquay, relates in his current annual report an outbreak of the disease in question due to the consumption of milk from a farm situated outside his own district. In commenting upon this Mr. Karkeek points out that when notification is not in

¹ Creameries and Infectious Diseases, by J. J. Welply, M.D., M.Ch. Q.U.I.

force the occurrence of cases of enteric fever amongst the milk consumers may be the first intimation that the disease exists at the farm or dairy from which the milk is derived; and even when notification is in force the obligation to notify does not extend to the districts in which the endangered milk is distributed. As a partial remedy for this state of affairs Mr. Karkeek recommends a system of compulsory cross notification—i.e., that the medical attendant shall notify to all the districts in which the milk from his patient's premises is distributed. We are afraid this suggestion would hardly be found to work in practice, more especially when applied to large towns where milk is frequently hawked about the streets and sold to persons whose names or addresses are quite unknown to the vendor. However, a discussion of the improvements which might be effected in the laws relating to the milk traffic would involve more space than we can at present devote to it. In regard to compulsory notification, it seems to us that its application to infectious disease occurring among the employes of dairies &c. would be but a partial solution of the problem, and that any additional legislation should extend to the notification of tuberculosis and eruptive diseases amongst the cows supplying the milk.

TWENTY YEARS AFTERWARDS.

MR. GAYLOR of Belper has for more than twenty years been medical officer of health for the Alfreton urban district. For looking after the sanitary status of 16,000 people he receives the by no means excessive remuneration of £50 per annum, and that he does his work well may be gathered from the fact that he has been re-elected annually since first appointed. However, *autres temps, autres mœurs*. The advent of the District Council has changed all this, and we learn from the *Alfreton and Belper Journal* that a member of the majority proposes to elect a new medical officer; also that before advertising the post the medical men in the town have been canvassed to know if they will be willing to stand for the post. Mr. Gaylor may say with the rejected suitor—

"Perhaps it was right to dissemble your love,
But why did you kick me downstairs?"

It is not alleged that he has neglected his duties in any way, and a more flagrant piece of injustice cannot be imagined. Here is a man who for twenty-two years has performed an arduous duty faithfully, and now he is to be superseded for what reason no one knows. That the other medical men in the town will reject the overtures of the council we feel certain, and we hope that the sense of fair play which is always said to be the characteristic of Englishmen will prevail and spare the Alfreton Council from being a by-word for injustice.

A REMINISCENCE OF THE FOUNDER OF "THE LANCET."

THE Speaker of the House of Commons has lately been appealed to with reference to the practice of members securing their seats by depositing their hats upon them at prayer time. A "political note" in the *Times* of March 5th recalls the fact that so long ago as fifty-three years a complaint was made with regard to the subject by a member of the medical profession, and our readers may be interested in knowing that the member of Parliament in question was the Founder of THE LANCET, "Thomas Wakley, Surgeon, M.P. for the Metropolitan District of Finsbury." (We quote from the title page of THE LANCET of 1842.) The following is the note in the *Times* which refers to Mr. Wakley: "Fifty years ago the securing of a seat at prayer time did not safeguard a member for the whole evening. On April 14th, 1842, Mr. Wakley publicly complained that, on returning to the House after an absence of two or three minutes, shortly before midnight, he found his seat occupied by an hon. member, who abruptly refused to give it up to

him; whereupon Speaker Shaw-Lefevre explained that any member, being at prayers, had a right to the seat he then occupied, but if he left it and went out of the House any hon. member might take it, and if it were given up it was a matter of courtesy, not of right. To remedy this anomaly a standing order was passed on April 28th, 1858, to the effect that any member having secured a seat at prayers be entitled to retain the same until the rising of the House. In 1880, Mr. Mitchell Henry having raised the question as to whether the putting of a hat on a seat did not mean 'a real working hat and not a colourable imitation,' Speaker Brand said the practice of placing a hat on the seat before prayers had prevailed for a considerable number of years, and the idea had always been that when so acting the member was in immediate attendance upon the House or on a committee. With regard to the retaining of seats with papers or gloves that had never been allowed." It will be noticed that the subject was reopened in 1880 by Mr. Mitchell Henry, who was also, curiously enough, a well-known medical man, being a Fellow of the Royal College of Surgeons of England.

A LAMENTABLE MISTAKE.

A SAD CASE of poisoning occurred last week at Skelmersdale near Ormskirk through the mistake of a druggist's apprentice. A woman went to purchase for her brother a black draught and received one ounce of tincture of opium in mistake, with the consequence of the death of the patient in about three hours. It appeared from the evidence at the inquest that the tincture of opium bottle was next to the black draught on the shelf in the shop, and the manager of the shop said so far as his experience went there was nothing unusual in keeping the opium next to the black draught or other harmless mixture and in a bottle of the same style and label as the rest. He said it would spoil the appearance of the shop to have bottles of different sizes and patterns, and appearance was of some importance, eliciting the appropriate remark from the coroner that "the lives of people are of some importance as well as the symmetry of a shop." There can be no doubt that if such customs do prevail in the ordinary druggist's place of business accidents or mistakes like this will take place. Surely a cupboard or shelves should be set apart, and could be, without spoiling the symmetry of a shop; and, besides, every bottle containing poison, such as tincture of opium, should have a distinct "poison" label on it. If this bottle had had such the purchaser would have seen the mistake being made. If it is requisite to dispense strong poisons in fluted bottles and label them "poison" it is equally requisite to adopt some plan by which mistakes such as that recorded above can be prevented.

CRIME AND ITS FACILITIES.

ON another page we publish the remarkable life history of a Spanish family, four members of which out of eight died violent deaths, either by their own or their neighbours' hands, while of the rest one only died "in his bed." We need hardly feel surprised if this catalogue of disaster should be regarded as suggesting the existence of a criminal constitution or family type. It is encouraging to find, however, that there is even among the class of experts devoted to the study of "crime" a divergence of opinion respecting the question of heredity in this relation. The resultant of such opinion amounts to a verdict of not proven and not probable. Mental and physical weakness, the depressing effect of poverty, numerous defects and frailties of character having a general significance, and climatic and racial variations even may exercise a certain influence upon character, but the true criminal type has not so far been plainly revealed as part of the mode and custom of moral evolution. Defective education has much to do with the matter, idleness

even more, nor should we omit to mention yet one other contributing factor—namely, the habit of carrying, needlessly in many cases, and using as freely, weapons of offence. The Spanish knife, indeed, may not always come under condemnation on this ground, and it is doubtless useful for many better purposes. Nevertheless, it is probably much less essential than it is believed to be by those who wear it. It has not been found to be equally indispensable by most other civilised peoples. Among ourselves there exists a no less indefensible custom, that of carrying superfluous firearms. Again and again have we been reminded of the reckless abuse associated with the pocket revolver, and the facts related by our correspondent and already commented on have a special interest as bearing upon this now familiar evil. We sincerely trust that the restrictive measure to which we alluded last week will before long be added to the Statute-book, and that it will by its practical success commend the principle of a general disarmament in regard to all similarly unnecessary weapons.

DIPHTHERIA IN LONDON.

THE deaths registered from diphtheria in London last week were 31 in number, an increase from 27 and 29 in the preceding two weeks. The corrected decennial average for the particular week is 29.6, exceeded last week by one. Only one of the deaths was in a person aged over twenty years, and 20 of them were in children aged from one to five years. Six were credited to Camberwell, 3 to Greenwich, and 2 each to St. Pancras, Islington, and Poplar sanitary areas. The removals to hospital numbered 43, less than half the cases having freshly arisen; and compare favourably with 49, 55, and 54 in the three preceding weeks. There were 463 patients suffering from the disease in hospital last Saturday, as against 500, 498, and 486 on the three Saturdays immediately preceding. In Greater London 9 deaths from diphtheria were registered, including 3 each in West Ham and Edmonton districts.

THE MUTILATION MARKET AND THE BUSINESS OF MENDICANCY.

AUSTRIA-HUNGARY is acquiring an evil pre-eminence in the manufacture of deformity and "lusus naturæ." Some eighteen months ago¹ we commented on the discovery made by the Croatian police of a regular mutilation den, where boys and girls of tender years were distorted or maimed to supply the mendicancy market—a den where by fracture or by continuous pressure between boards tightened by screws the legs and arms and spinal columns of these poor little victims were made to assume monstrous shapes—where even the eyes were gouged out and artificial sores created—all to provide the traffickers in street-begging with "objects" wherewith to solicit the alms of the benevolent. The arrest and severe punishment of these purveyors of deformity seems, however, to have put no effective stop to the practice, for we read in a Hungarian journal that "at Prague a man, Proschaska by name, was taken into custody charged with selling to the firm of Ritter and Munster of Holstein a number of children who, by means of specially contrived alimentation, had had their growth arrested for exposure as 'Lilliputians' in itinerant exhibitions." For every child so stunted and maltreated the sum of 300 florins was paid. We further read that not only were the authors of the "Lilliputianising" system brought to justice, but also the unnatural parents who consented to its being applied to their offspring and who received money for doing so. This is, of course, quite commendable on the part of the law, but we fear its heaviest punishment will have small deterrent force so long as the

public do not coöperate in suppressing the "business of mendicancy." Indiscriminate almsgiving lies at the root of the whole evil. Rather than take the trouble to ascertain where relief can most worthily and effectively be bestowed the so-called "benevolent" man will lavish his small change on every beggar who crosses his path, thereby creating half a dozen similar beggars for every one he subsidises and depriving the really well organised charities of the funds of which they are sorely in need. One of the most large-hearted economists of his generation, Archbishop Whateley, congratulated himself at the close of his life that he never gave a penny to a beggar, but that the money withheld from such objects had been profitably bestowed on the institutions, medical and other, where succour was vouchsafed only to the deserving. If the public acted with equal wisdom and stiffened its back against the professional mendicant while relaxing its pursestrings in support of well-accredited charities, an end would speedily be made of the "business of beggary" with all its concomitants of "mutilation dens" and "Lilliputian farms," and "lusus naturæ" manufactured and supplied to order. We hope the subject will be adequately discussed at the International Congress for the Protection of Infancy which will meet next July at Bordeaux.

THE UNIVERSITY OF CAMBRIDGE AND THE EXTENSION OF SCIENCE TEACHING.

PROFESSOR CLIFFORD ALLBUTT, in a letter published in another column, calls attention to a very reasonable method of extending university teaching which is contemplated this summer by the University of Cambridge. Members of the medical profession are invited to attend courses of lectures and demonstrations upon the scientific side of their professional work, and facilities are to be granted to them which should make their visit to the university town not only instructive but inexpensive and pleasant, as an insight into Cambridge collegiate life will certainly be among the things to be gained in a programme which provides for residence in college. The question of the advantages and disadvantages of the extension of university teaching is a very large one, into which we do not propose to enter; but the departure for which the various professors of science at Cambridge are responsible seems to us not only free from all objection but worthy of all praise, and we are certain that their invitation will be promptly replied to.

OYSTERS AND TYPHOID FEVER.

AN interesting note on this subject appears from the pen of Mrs. Percy Frankland in *Nature*.¹ She points out that De Giaksa some years ago found that in ordinary sea water the typhoid bacillus suffered very considerably in the competition with the numerous other water bacteria present; but it was still identified on the ninth day, and in other specimens it could be detected on the twenty-fifth day after it was introduced. Cassedebat, an investigator in the same field, found, however, that whilst many pathogenic bacteria, including anthrax and cholera, lived for many days, typhoid bacilli were destroyed in the course of forty-eight hours in sterilised sea water. On this point Professor Percy Frankland has made some interesting observations to the effect that the addition of 1 and 3 per cent. of common salt to ordinary Thames water into which typhoid bacilli were introduced acted very prejudicially on the latter, although it stimulated the multiplication of many forms of water bacteria. De Giaksa also experimented with fish, introducing pathogenic microbes by the mouth; but he selected only cultures of cholera and anthrax bacilli for this purpose, with the result, however, that in both cases these micro-organisms were entirely destroyed in a few hours. In the greater bulk of the

¹ THE LANCET, Aug. 26th, 1893.

¹ Feb. 28th, 1895.

experiments made with oysters and some varieties of mussels, replaced in sea water after inoculation through a hole in the shell which was afterwards sealed up, he found that the pathogenic microbes (cholera and anthrax) had entirely disappeared in six hours, whilst in only two instances were they detected in small numbers at the end of twenty-four hours, and in no case were they identified after forty-eight hours. From these results there would appear to be no evidence that these pathogenic microbes are capable of being transmitted by means of these shell-fish; but, as the writer suggests, the subject might well claim reinvestigation, especially in regard to oysters as possible transmitters of typhoid fever.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

DR. ARTHUR NEWSHOLME will deliver the third and fourth Milroy Lectures on Tuesday, March 12th, and Thursday, March 14th, respectively, on the Natural History and Affinities of Rheumatic Fever. The first two lectures we are pleased to be able to reproduce in full in our columns this week. Dr. H. D. Rolleston will deliver the Goulstonian Lectures on the Suprarenal Capsules on Tuesday, March 19th, Thursday, March 21st, and Tuesday, March 26th, respectively. Dr. G. Fielding Blandford will deliver the Lumleian Lectures on the Diagnosis, Prognosis, and Prophylaxis of Insanity on Thursday, March 28th, Tuesday, April 2nd, and Thursday, April 4th, respectively. All the lectures will be delivered as usual at the College, Pall Mall East, at 5 P.M.

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

WE have received from Mr. J. Wickham Barnes the following copy of a petition, which is to be presented to the House of Commons shortly:—"To the Honourable the Commons of Great Britain and Ireland. The humble petition of the Poor-law Medical Officers' Association. Sheweth: That your petitioners are an Association representing the Poor-law medical officers of Great Britain. That notwithstanding the present equitable claims of Poor-law medical officers to superannuation under existing Acts of Parliament, your petitioners are ready to contribute a percentage deduction from their salaries and emoluments in order to secure certainty of superannuation to every Poor-law medical officer." All Poor-law medical officers who have not yet sent in their petitions to Mr. Wickham Barnes, hon. secretary of the Association, are earnestly requested to forward them to the Member of Parliament of their district for presentation before March 15th. We trust that the House will see their way to grant so reasonable a petition, feeling sure that they must see, as we do, that in every branch of public service the most obvious method of raising the standard of the officers—and so ensuring the best work—is to give to these officers that stability of position which can only be ensured by security as to their pecuniary future.

THE LATE MR. HULKE.

THE funeral of the late President of the Royal College of Surgeons of England took place on Saturday, Feb. 23rd, at Deal. Mr. Alfred Willett and Mr. Cowell represented the Royal College of Surgeons of England; Dr. J. Kingston Fowler, Mr. A. Pearce Gould, and Mr. G. H. Lock (house surgeon), the Middlesex Hospital; Dr. Sims Woodhead, the Laboratory Department of the Conjoint Board of the Colleges of Physicians of London and of Surgeons of England; Mr. Reginald Harrison, the Royal Medical and Chirurgical Society; Mr. John Langton and Dr. C. Holman, the Clinical Society; and Mr. Lydekker, F.R.S., the Geological Society. The service at Deal was conducted

by the Rev. Bruce Payne. Simultaneously a service was held at St. James's, Piccadilly, at which the Royal College of Physicians of London and other institutions with which the deceased was connected were officially represented. Among those present were Sir William Savory, Bart., F.R.S., the life-long friend of the deceased, so soon, alas, to follow him; Sir James Paget, Bart., F.R.S.; Sir William MacCormac, Mr. Birkett, Mr. Bryant, Mr. Butlin, Mr. Andrew Clark, and Mr. Trimmer, the secretary of the Royal College of Surgeons of England. The Royal College of Physicians was represented by the President, Sir J. Russell Reynolds, Bart., F.R.S.; the Censors, Dr. Pye-Smith, F.R.S., and Dr. T. T. Whiphram; and the Treasurer, Sir Dyce Duckworth. Among those present, but in unofficial capacity, were Sir George Johnson, F.R.S., Sir William Priestley, Sir George Buchanan, F.R.S., Dr. Allchin, Dr. Norman Moore, Dr. Pavy, F.R.S., and Dr. Douglas Powell. The Rector (the Rev. J. E. Kempe) conducted the service and gave a short address, in which he referred sympathetically to Mr. Hulke's long connexion with the parish.

THE WATER-SUPPLY OF CHESTER.

THE report of the Special Committee of the Chester Town Council, which was issued two months since, has not long been allowed to go unchallenged. Dr. W. M. Dobie, in an interesting and exhaustive letter in the *Chester Courant*, traverses many of the important conclusions to which the committee came. After indicating some of the defects in this report he expresses the opinion that an adequate supply of pure water from wells beyond the city and also from a point in the river above Farndon could most probably be obtained. While we agree with Dr. Dobie in his general remarks upon the value of chemical and bacteriological analysis of water, we must point out that the example of a chemical analysis of water which he quotes is hardly fair, since it does not contain a single item upon which a trustworthy opinion, from a sanitary point of view, could be based. His statement also in regard to the vitality of the bacillus typhosus in sewage water would appear to require modifying in view of the results of recent research. Taking it as a whole, however, Dr. Dobie's letter seems to us to establish a pretty fair case.

THE NEW (P) STREET DANGER: A CURIOUS POSSIBLE CAUSE.

A VERY remarkable observation, which may throw light upon the cause of the recent explosions in electric light boxes in the streets, appears in a letter addressed to the chairman of the St. Pancras Electric Light Committee by the Board of Trade. It is that Major Cardew, the electrical adviser of the Board, has discovered in his investigations that a remarkable deposit on some of the insulators contained a considerable quantity of the metal sodium. In the absence of further evidence upon this point it is impossible to account for this singular occurrence; but, of course, the electrolysis of a sodium salt is indicated, and it would be interesting to know whether the materials used in insulation contained any fusible salt of sodium such as, possibly, borax. At any rate, the manufacture of sodium under the pavements of the streets in this perfectly indiscriminate way is exceedingly dangerous, and demands prompt repression. To this end we are glad to learn that the Board of Trade have asked the assistance of the Royal Society and of the Institute of Electrical Engineers in order to investigate the causes leading to the formation of this substance, and thus to set at rest what at first sight appears to be a chimerical view. In the meantime the primary cause of the recent explosion cannot be accepted as having been satisfactorily decided. It may be coal gas, or it is just possible that the gas is derived from the distillation of gases out of the bituminous insulating material by the over-heating of the

cable. In one instance (at Leicester on Feb. 13th) the electric gas engineer attributed the explosion to the oil used in the insulating material having become "gasified" by the electric arc. In any case the boxes should be properly ventilated, and the air space reduced as far as practicable by filling them up with some inert material, much in the same way as the culverts built over high pressure gas mains for the purpose of getting to the mains and clearing them of obstructions are filled. If, again, it is shown to be due to defects in the gas main, pressure should, of course, be brought to bear upon the gas companies to have these defects remedied. It is reasonable, however, to suppose that the gas companies are just as anxious to prevent leakage and waste of their gas as everyone must be to learn of the discovery of an effective provision against any future occurrences of this kind, which experience has shown may imperil life and limb.

NIGHT SHELTERS FOR THE DESTITUTE.

THE recent exceptionally severe and prolonged frost has caused intense suffering among the unemployed and destitute classes, who will probably for some time yet be unable to resume their uncertain and precarious occupations. Philanthropic workers among these unfortunates recognise the primary necessity of protecting them from the inclement weather during the night as well as of providing a small allowance of food. Such a free refuge for the hopeless and despairing has been established in Phoenix Hall, Carlton Vale, in the north-west of London, and each night it affords a shelter to about 600 men. Financial help is greatly needed, and subscriptions will be thankfully received by Miss F. Ashdown, 27, Kilburn-park-road, N.W. Two Sisters of the Church attend at the hall every night to receive the applicants for admission, many of whom are in a truly woeful state.

THE MEATH HOME FOR FEMALE EPILEPTICS.

THE second annual report of the Meath Home of Comfort for Epileptics at Godalming will be read with interest by all who are seeking to benefit this unfortunate class. At this home only female epileptics are admitted, the limits of age being two years and thirty-five. The plan of treatment is to provide bright and healthy surroundings and suitable useful occupation, treatment by drugs taking a secondary place. Needlework, knitting, and basket-work are the occupations which are chiefly followed, and the proceeds of the sale of the manufactured articles form an important item in the receipts of the home, amounting, together with those from the sale of garden produce, &c., to upwards of £100. The report by the medical officer shows a marked improvement in the health of most of the cases admitted. We regret to see that the home is crippled for want of funds. Six inmates had to be discharged in consequence of fees falling, there being a very limited number of free beds. It is to be hoped that so excellent a movement will not fail to receive warm and generous public encouragement. All subscriptions may be sent to Colonel Clarke, R.E., Uphill, Warren-road, Guildford.

THE DIFFUSION OF SMALL-POX.

THROUGHOUT the United Kingdom the news coming to us in respect of last week concerning the prevalence of small-pox is of a most reassuring character. In London there were but 8 new cases and 1 registered death—namely, that of a person between the ages of twenty and forty belonging to the Newington sanitary area, and as to whose vaccination no statement is forthcoming. All the 8 cases were removed to hospital, the institutions of the Metropolitan Asylums Board containing at the close of the week 68 patients, as compared with 58, 67, and 75 on the three preceding Saturdays. One or two cases in suburban districts are recorded. In the rest of

England there were a few attacks at Birmingham, Liverpool (where also 1 death was registered), and at a small number of other Lancashire towns. In the third week of February there were 2 deaths from small-pox in Edinburgh, and in the same week there were 6 deaths in Dublin. Of these, 2 were in vaccinated persons, aged respectively eighteen and thirty-eight years, and 4 in unvaccinated individuals, aged twenty days, twenty-one days, twenty-eight years, and thirty-three years respectively. The admissions to hospital, which had been 69, 60, and 56 in the three preceding weeks, fell further to 37, and were exceeded by the discharges, which were 44; the patients remaining under treatment being 135, in addition to 119 convalescents at the South Dublin Union small-pox hospital at Kilmmainham. The total of 254 thus made compares favourably with recent records.

PROPOSED ASSOCIATION OF QUALIFIED MEDICAL ASSISTANTS, JUNIOR MEDICAL OFFICERS, AND LOCUM-TENENTS.

WE are desired by Mr. T. Howard Brocklehurst, who is acting as organising secretary, to announce that a meeting in connexion with the proposed Association of Qualified Medical Assistants, Junior Medical Officers, and Locum-tenents will be held on Monday next, the 11th inst., in the Examination Hall, Victoria Embankment, at 3 P.M. Dr. J. G. Glover will preside, and all interested in the matter are invited to attend. In announcing this meeting we beg to refer our readers to a letter from Mr. Brocklehurst which appeared in our columns on Jan. 5th of this year, and to our leading article in the same issue. Mr. Brocklehurst's letter gives the reasons for his belief that the new departure would work for general professional good, and our article endorses, with certain limits, his views. We are happy, therefore, to assist the movement by recommending to all concerned that they should attend the meeting and assist in placing the proposed association upon a definite basis.

THE COUNTY COUNCIL ELECTION.

THE medical profession of London was by no means unrepresented at the election for the London County Council, which took place on Saturday last; but we should have been glad to see our professional brethren in larger numbers before the constituencies. Seven medical practitioners presented themselves as candidates for election, and of these no fewer than five were returned. The seats so filled are Bermondsey, occupied by Mr. G. J. Cooper; Greenwich, by Dr. Ralph Gooding; North Hackney, by Dr. E. B. Forman; West St. Pancras, by Dr. W. J. Collins; and Wandsworth, by Dr. G. B. Longstaff. In every one of these constituencies, as, indeed, throughout the metropolis, there was a contested election, and in every instance the medical practitioner came in at the head of the poll. Four of the five, that is to say all save Dr. Gooding, sat upon the last County Council, so that they were known to their constituents and will be familiar to their work. Dr. Gooding was a candidate for a constituency within which he is resident, and has received the suffrages of his neighbours. We congratulate both him and them upon his accession to this new sphere of usefulness. The medical element in the County Council has not received any increase of strength on the present occasion, for the addition of Dr. Gooding to its ranks is balanced by the loss of Mr. H. Harris who sat for Brixton in the last Council, and whose name, as well as that of Mr. Gibson Bott, we regret to miss from the new muster-roll. We should have been glad, as we have said, to see a more adequate representation of the art of medicine in the ranks of the councillors, for, having regard to the very large proportion of the Council's work which bears directly or

indirectly upon the public health, we cannot regard the proportion of five members out of 118 as at all adequately representing the interest which the medical profession takes, and is bound to take, in the management of London municipal affairs. This becomes very evident if a thought is given to the immense amount of work which devolves upon the committees of the Council—work which, although done in comparative obscurity, is of the greatest importance to the community and makes proportionate demands upon the time and attention of the members. At present the institution is new, and can hardly be said to have got into steady working order. Practical aims and practical men are elbowed aside to some extent by politicians and theories; but as time wears on, and the functions of this body become more clearly defined and its ambitions more circumscribed, we confidently expect to see medical practitioners taking a growing share in its labours, and, we may add with equal confidence, in its successes.

SIR FRANCIS WYATT TRUSCOTT.

By the death of Sir Francis Wyatt Truscott the City of London has lost one of its representative public men. The deceased knight suffered from bronchitis and asthma, and died on March 3rd after a short illness. Born in Truro in 1824, he was admitted to the Corporation of London as a Common Councilman in 1853, and in 1871-72 he and Sir John Bennett were sheriffs. As many of our readers will remember, it was during this period that the Prince of Wales safely passed through his very severe attack of enteric fever, and the national thankfulness for this happy result found expression in various ways, which in the City took the form of a Thanksgiving Service in St. Paul's Cathedral, attended by the Queen and the Royal Family, and followed by a display of illuminations in the evening. Both sheriffs were knighted in recognition of their services on this occasion. In 1871 Sir Francis Truscott became Alderman of Dowgate Ward, and in 1879 he was elected Lord Mayor, his term of office being marked by several important civic events, and by his elevation to the office of Grand Warden of Freemasons, in which capacity he entertained the Prince of Wales, the Grand Master, and other dignitaries of the craft at a Mansion House banquet. Sir Francis Truscott was a member of the firm of Messrs. James Truscott and Sons, printers and stationers; besides his services to the Corporation he filled many public positions of honour and responsibility. He rendered great services to the cause of the Metropolitan Hospital Sunday Fund, and it is for this reason more especially that we feel that his death should be not unrecorded in the columns of THE LANCET.

THE INFLUENZA EPIDEMIC.

It may reasonably be hoped that the influenza epidemic prevailing in London is now on the decline, although the character of the disease and its obvious relationship to grave pulmonary affections will, we fear, be evidenced in the heightened death-rate for a few weeks to come. One feature of the present recrudescence of the disease—for it has not been entirely absent from this country since its appearance at the end of 1889—is the irregularity of its incidence, contrasting with the far more orderly march of the great pandemic wave which traversed the globe five years ago. We hear of its appearance in certain great Continental cities, but without any evidence of its being conveyed from one to the other. This would accord with the view that the influenzal germ or virus still persists in places where it was introduced at the time of the pandemic, and that some local conditions have served to bring about its renewed activity and virulence. Here in England the phenomenal frost, which has coincided with the out-

break, suggests a heightening of individual susceptibility to the disease from the depression of vital powers produced by the influence of cold. But hitherto no concordance has been established between the prevalence of influenza and exceptional climatic conditions, at least in the manner suggested by the above hypothesis. In his admirable study of the mortality from influenza which appears in the current volume of the Epidemiological Transactions, Dr. Franklin Parsons shows that since the disease reached this country from the East at the close of 1889 there have been in all five epidemics, notably in London—namely, (1) in the winter of 1889-90, (2) in the spring and summer of 1891, (3) in the winter of 1891-92, (4) in the spring of 1893, and (5) in the winter of 1893-94. Each of these outbreaks arose with marked suddenness and rapidly culminated, although the later ones declined more slowly than the earlier. As Dr. Parsons points out, the character of the disease in this respect has been approaching rather to that of an endemic disease with seasonal prevalence. We would, however, fain hope from what epidemiology teaches that influenza has not come to stay as an endemic in these islands. It is true that it has already persisted longer than previously recorded outbreaks would suggest, and there is, indeed, no *a priori* ground for rejecting the notion that it may become as fixed a habitant as measles or scarlet fever, having, like them, periods of epidemic prevalence, governed doubtless by some laws or conditions as yet unknown. As regards the mortality attributable directly to influenza, we would remark that when, as at present, the outbreak coincides with states of weather favourable to respiratory disease, there is risk of attributing to influenza itself a far greater virulence than it actually possesses. The advent of more genial weather will operate in diminishing the mortality from respiratory affections, and in hastening the convalescence of those who have been subjected to the depressing action of the virus of influenza.

THE LATE PROFESSOR BLACKIE.

EDINBURGH and her school have sustained a severe loss in the death of this kindly scholar and brilliant man of letters. "An Old Pupil" writes:—"For thirty years John Stuart Blackie held the Greek Chair in our University, and if he did not turn out a generation of Porsons and Hermanns he certainly threw the charm of Hellenic literature and art round the mental equipment of thousands of young aspirants to all the professions. More a man of letters than a philologist, though by no means inadequate on this latter side, he sought to make Greek a living influence even in the case of those who had no leisure or capacity for the language. He was the life and soul of that private symposium peculiar, I believe, to Edinburgh, at which old pupils and advanced professional men assembled in rotation at each other's houses to read and discuss the master-works of Greek poetry or speculation. The medical calling was largely represented on those occasions, and the genial friction of mind with mind which the readings called into play had a wonderful effect in relieving the restrictive influences contracted by absorption in purely professional work. Of no calling was Professor Blackie more cordially enamoured than the medical, constantly attending the meetings of the Medico-Chirurgical Society and interesting himself with something more than the enthusiasm of an enlightened amateur in the great problems emerging from time to time in the development of the healing art. The last time I met him was in London, when he surprised and delighted the company with his exposition of the Hippocratic treatise on Air, Water, and Locality, and made himself instrumental on the occasion in bringing to the notice of the medical scholars present the recently published biography of the

great critic and physician, Adamantios Koraïs, the modern Greek who graduated in medicine at Montpellier and left an epoch-making mark on Hippocrates and other classics. He was at the head of every liberally devised scheme for university extension, and the Edinburgh school owes it largely to him that it keeps so vigilantly in touch with academic progress, not only in literature but in science, particularly as reinforced from abroad."

DEATH OF DR. HACK TUKE.

WE regret to have to announce the death of Dr. Hack Tuke, which took place at his residence, 63, Welbeck-street, on March 5th, from cerebral hæmorrhage. Owing to the extreme pressure on our space this week we are compelled to defer the publication of an adequate biographical notice until our next issue.

A MEMORIAL of the late Dr. Francesco Gasco, Professor of Comparative Anatomy and Embryology in the University of Rome, whose brilliant career we sketched in THE LANCET of Nov. 3rd, 1894, is in active progression. Its promoters include the most distinguished names among his colleagues, as well as those of many old pupils now holding professorships in the various Italian schools. It will take the form of a monument to be erected over his tomb in the Campo Verano.

OUR special articles dealing with the Difficulties under the Infectious Disease (Notification) Act have been reprinted in pamphlet form, and the pamphlet will be sent post free at a charge of sixpence upon application to the office. The reprint has been undertaken as a practical response to the many questions which have reached us concerning the points raised by the articles.

HIS ROYAL HIGHNESS THE DUKE OF CAMBRIDGE has consented to take the chair at the festival dinner of the National Hospital for the Paralysed and Epileptic, Queen-square, which is to be held on Tuesday, April 2nd, in the Whitehall Rooms of the Hôtel Métropole at seven o'clock.

MR. S. L. HINDE, L.S.A., who so ably assisted in a recent campaign against the Arab slave raiders on the Upper Congo, will lecture on his three years' travelling and fighting experiences in the Congo Free State before the Royal Geographical Society on Monday next, March 11th.

WE regret to learn the death of Mr. Charles Edward Armand Semple, M.B. Cantab., M.R.C.P. Lond., Physician to the Royal Society of Musicians and Secretary to the Court of Examiners and Board of Examination in Arts of the Apothecaries' Society of London.

WE are sorry to announce that Dr. R. C. A. Prior, the Senior Fellow of the Royal College of Physicians of London, is suffering from a very severe attack of influenza.

WE have heard with deep concern of the death of Mr. Charles H. Robinson, M.R.C.P., F.R.C.S. Irel., of Kingstown, who was a frequent contributor to our columns.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—The annual meeting of governors was held on March 1st at the hospital in the Marylebone-road, Major McMahon presiding. The committee's report stated that H.R.H. the Duchess of York has graciously consented to become a vice-patron of the hospital. During 1894 there had been 1079 in-patients and 1318 out-patients. The expenditure had exceeded the income by £1571.

PARLIAMENT AND PRISON REFORM.

(FROM A CORRESPONDENT.)

FOR some time past much dissatisfaction has been expressed concerning the administration of English local prisons. There have been deputations to the Premier and to the Home Secretary from representatives of societies that seek to assist discharged prisoners, and articles have appeared in the magazines and the newspapers. As a result of these complaints Parliament appointed last summer a committee to inquire into the matter. This committee, under the presidency of Mr. Herbert Gladstone, has already held about a dozen sittings. Among its members we note the names of Dr. Bridges and Sir John Dorington, M.P. The latter gentleman is a county magistrate, and this is important, because the Prisons Act of 1877 has always been looked upon with considerable disfavour by county magistrates. This Act completely deprived them of all responsibility in the management of prisons, yet it left them a semblance of power by giving them the right of inspection &c. All real power was centralised by the Act at the Home Office. Such centralisation has naturally destroyed the local interest formerly felt in the fate of prisoners, with, it is maintained, very disastrous results on the health of the inmates of local prisons. The prevalence of insanity in English prisons has doubled and the death-rate is much higher than in Irish prisons. These are weighty facts and alone suffice to justify the holding of a Parliamentary inquiry. It may, nevertheless, be urged that the death-rate in English prisons has decreased. In reality, however, the facts may not be what the figures seem to indicate. On p. 24 of the seventeenth report of the Prison Commissioners we find allusion to a circular from the Home Secretary to the magistrates, and it will be seen that formerly a large number of prisoners were committed in a moribund condition. Now such cases are not sent to gaol, and this contributes to reduce the death-rate. Also it is now more generally the practice to release prisoners who are in a dying condition before the expiration of their term. All this naturally very materially contributes to reduce the death-rate, but it does not mean that the prisons are more healthy or that the system of management is more conducive to the preservation of life. On the contrary, since the centralisation and the more bureaucratic management of prisons we have had a rigorous assimilation of régime, which is certainly contrary to all physiological facts. It is preposterous to suppose that identically the same quantity and quality of food, clothing, and exercise will suit equally well an agricultural labourer and the weak degenerate worker from a sweating den or an unwholesome and overcrowded slum of a big city. Nor is the climate of every part of England so identically alike that exactly the same food and clothing will do for every prison. Also there are the sanitary conditions, the soil, the drainage, the warming, the ventilation, which differ in the various prisons; and a prison dress which is ample in a dry well-warmed prison is quite insufficient where dampness prevails and the warming methods are defective. Formerly, when the prisons were under local management, there was a much greater elasticity in the rules applied, and there were modifications in diet and clothing to suit special local and individual conditions.

That there must be something radically wrong in the management of English local prisons will be admitted when the death-rate is compared with that of the Irish prisons. The average annual death-rate in the Irish prisons during the ten years 1883-84 to 1892-93 was equal to 4.15 per 1000, while in the English local prisons it amounted to 7.7. The report of the Parliamentary committee should explain why there is so notable a difference between the Irish and English prisons. It certainly will be urged that the treatment of the Irish prisoners is at once more humane and more in keeping with physiological laws. There is one fact that stands out in bold relief—namely, that the punishment-rate is much lower in the Irish than in the English prisons, and furthermore, that in Ireland there is no corporal punishment inflicted for offences committed while in prison. In England, in 1893-94, no less than 98 prisoners were flogged for bad conduct while in prison, and 87 were put in irons. In Ireland there are no irons, though sometimes leather straps or a sort of muff are used, but even this milder form of punishment is not so frequently employed as the irons in England. The question

arises whether there is not some connexion between the high rate of punishment and the high rate of mortality in English local prisons. It must be borne in mind that ordinary imprisonment is, at best, a very severe physical trial. When, however, this is aggravated by a large amount of prison punishment the consequences may be serious. Punishment involves confinement in cells, reduction of diet, and loss of stage privileges; it means solitary confinement in dark cells and no exercise. Assuredly this sort of punishment must reduce the vitality of the prisoners, and there were upwards of 30,000 such penalties inflicted in the English prisons during the year 1893-94.

Some attempt has been made to show that the prison treatment cannot be so very bad, as it is not the old prisoners who commit suicide. Nothing can be more erroneous than this statement. It is said that in the five years ending March, 1893, there were in all 43 suicides in the prisons. Of these, 16 occurred within one week of imprisonment, 9 within two weeks, 5 within a month, 5 within two months, 3 within three months, and only 2 after twelve months' imprisonment. From this one is led to believe that suicides are much more frequent among persons condemned to short terms, or who have not yet acquired any experience of prison life, and who kill themselves from apprehension of what it may be rather than from actual knowledge. Yet any statistician must know that such matters must be judged, not by the actual number of suicides, but by their proportionate relation to the number of persons concerned. Thus, for instance, in the year 1893-94, there were 161,641 persons sentenced to imprisonment. Out of this number, however, only 680 were sentenced to terms of over a year. Two suicides out of 680 persons is a much higher proportion of deaths than 41 out of the remaining 161,161. From the 43 suicides must be deducted not only the 2 suicides that occurred after a year's imprisonment, but also 19 suicides of prisoners under remand awaiting their trial. These latter were not exposed to the full rigor of prison discipline and diet. There thus remain 24 suicides committed by convicted prisoners before they had undergone twelve months' imprisonment, as opposed to 2 suicides after twelve months; and these two suicides, as compared to the very small number of persons in prison for more than twelve months, represent much the highest death-rate from suicide. As for the ordinary death-rate, it will be found that probably more than half the prisoners who die in prison are old offenders. The proportion is greater than that shown by the actual figures given, for in some cases previous convictions are successfully concealed. In 1894 there were 111 prisoners died, and 69 or 70 had undergone previous sentences of imprisonment. This seems to indicate the fatal effects of repeated imprisonment.

With regard to the very alarming increase of insanity among prisoners, it is remarkable that, though the number of previous convictions is given in the death-rate, no similar figures exist relating to the number of convictions in cases of insanity. It is, therefore, not possible to check the assertion made that, out of 354 prisoners declared to be insane in 1893-94, only 20 had been previously imprisoned. This seems most unlikely, for it so happens that the cases of previous imprisonment are incidentally recorded in the report received from Holloway Gaol. There we find that, of the prisoners who became insane in Holloway Gaol, 15 had been in prison before. Thus, if the number 20 is correct, this only leaves 5 prisoners for all the other prisons of England who can be described as having undergone previous imprisonments and as having become insane. Again, the question might be asked why is there not a comparative summary of insanity among prisoners during the different years? It is only by looking at the judicial statistics that one discovers the frequency of insanity has doubled under the present centralised system of management. In the face of such circumstances it may be asked whether the prison authorities have consulted experts on mental disease. It is understood that Mr. Lewis of the Wakefield West Riding Asylum and Dr. Claye Shaw have been before the Parliamentary committee. Evidence has been taken on the cellular system, the restriction of prison industries and their effect on the increase of insanity. From my knowledge of the subject, and what such authorities as the above medical witnesses are likely to think, I feel convinced that they will have condemned the present manner of applying the cellular system.

A great deal of valuable evidence has been obtained by the Parliamentary committee. Their labours are not likely to terminate soon, as the scope of their reference has been

extended. Under these circumstances would it not be well to publish the evidence already collected? The public have good reason to be anxious about the matter, and perhaps fuller information would be forthcoming if more was known of what is now being done. So far as the inquiry has actually gone, the results, we have good reason for believing, seem to point to the probable breaking down of the bureaucratic system at the Home Office. Then efforts will be made to introduce a different method of dealing with juvenile offenders, to establish a more rational classification of prisoners, to extend industrialism, and to relax the rigidity of the cellular system. It is also well nigh certain that improved and more varied diet will be proposed, more especially in the earlier stages of imprisonment. What with the very scanty diet and the further reduction in the amount of food as a form of punishment for breach of prison discipline, the prisoners, it is maintained, are reduced to such a state of weakness that it often happens they leave prison physically unfit for work. This, in any case, is the opinion of such authorities on the subject as Mr. Wheatley of the Brook-street St. Giles Mission to Discharged Prisoners and of the officers of the Salvation Army barracks, who are constantly seeking to assist discharged prisoners. These men come out of prison in a dazed condition and are too often totally unfit for work. Consequently many are driven by sheer necessity to steal and thus again fall into the hands of the police. This explains the great increase of recidivism, which is another cause of complaint against the present system of prison administration. Certainly reform as well as punishment should be the object of imprisonment, and reform which is unmindful of physiological laws cannot be effective. If a prisoner when discharged is to earn an honest livelihood he must have the health and intelligence to work. Neither the one nor the other can be engendered by solitary confinement and insufficient food and exercise. It is difficult to say how far a criminal is responsible for his actions or how far he is the victim of inherited tendencies and vicious surroundings. To reform such persons great powers of observation, a quick appreciation, and deep knowledge of human character, combined with infinite tact, are necessary. These rare qualities are not easily found, and certainly the ordinary prison gaoler cannot be expected to display such subtle understanding. For the most part gaolers are old soldiers. They are not well paid, and sometimes they are very much overworked. It is natural that they should occasionally vent the ill-humour these hard conditions engender on the prisoners in their charge. Perhaps if the truth could be ascertained it would be seen that many a prisoner has been punished for infringing prison discipline or for committing some other offence of which he would not have been guilty if he had been treated in a more judicious manner by his gaoler. It may also happen that prisoners fail to obey rules &c., not from malice prepense, but because they are in a semi-demented condition. But the gaoler who is a mere military martinet is not able to distinguish between a weak-minded and rebellious or disobedient prisoner. The gaoler does not pause to make psychological studies, he just carries out the rules with rigid inflexibility, as if every human being was identically alike. As a result, evil dispositions are aggravated instead of being checked and modified. Then follows punishment upon punishment, notably solitary confinement, with the encouragement it gives to the secret vices that lay the foundation of insanity. Thus, under the present system of management, as already stated, the prevalence of insanity in local English prisons has doubled, the death-rate is nearly twice as high as in Irish prisons, and recidivism is on the increase. Evidently there is urgent need of reform, and it is desirable that the Parliamentary Committee should press forward its inquiry and suggest practical remedies.

ARMY MEDICAL DEPARTMENT REPORT FOR 1893, WITH APPENDIX.

[SECOND NOTICE.]

It is of course impossible to do more than refer to some of the more salient points in noticing a voluminous official report of this kind, and while that for 1893 may be said to be, upon the whole, of high average merit, there is happily no important epidemic or serious outbreak of disease recorded

for that year, or any subject of such special interest as to claim particular attention. The health of the troops serving in the United Kingdom was favourable. The most important statistical ratios of sickness and mortality are shown in the following table, calculated as regards deaths and invaliding on strength including men detached:—

	Ratios per 1000 of strength.			
	Admissions.	Deaths.	Invaliding.	Constantly sick.
England and Wales...	790.8	5.43	16.14	46.90
Scotland	628.5	6.11	18.06	26.92
Ireland	652.5	4.13	14.11	38.21
United Kingdom...	751.6	5.13	15.70	44.10

Compared with 1892, the admission-rate in England and Wales shows a decline of 1.6 per 1000, the death-rate an increase of 1.00, and the constantly-sick rate an increase of 1.95. While the admission-rate has declined by 13.2 per 1000, the death and constantly-sick rates show a fractional increase as compared with the average ratios of the preceding seven years. The admission, death, and constantly-sick rates in Scotland are all rather higher than those of the previous year, but less than those of the preceding seven years, except the death-rate, which shows an increase of 0.59 per 1000. In Ireland there is a decline in the admission, death, and constantly-sick rates of 48.5, 0.09, and 0.93 per 1000 respectively, and there is also a decrease in the admission, death, and constantly-sick rates in 1893 as compared with those for the previous seven years. Taking the United Kingdom as a whole, the admission-rate shows a decline of 9.7 per 1000, as compared with 1892; the death and constantly-sick rates have, however, slightly increased—0.75 and 1.35 respectively; but there is a decrease in all these rates as compared with the previous ten years.

In England and Wales there were 103 admissions and 16 deaths in 1893 from enteric fever; in Scotland only 3 admissions, and in Ireland 45 cases and 6 deaths. The largest number of cases in any station was at Aldershot—49 cases and 9 deaths. Most of the cases arose in the Marlborough lines, and their occurrence, we are told, became the subject of investigation by a special committee. Out of 45 cases reported in Ireland 25, with 3 deaths, occurred in Dublin. "The exact cause is not known, but Dublin, as stated in last year's report, is notoriously unhealthy where enteric fever is concerned."

Taking all forms of venereal disease together the admissions from this cause were 19,484, and the average number constantly sick 1670.02, the total admission ratio being 194.6 per 1000, and the constantly-sick rate 16.63. This represents a very large amount of inefficiency, but as compared with previous years the rates seem to have, on the whole, decreased. The greatest prevalence of these diseases was in the Channel Islands, the Home, Eastern, Woolwich, Western, and Dublin districts. The lowest rate was in the Cork district—86.3 per 1000. An increase in the admission-rate, as compared with last year, is observed in eight districts, especially in Belfast, Dublin, and Aldershot.

We need not do more than refer to the tables which have been prepared to show the influence of age and length of service on sickness, mortality, and invaliding among the troops in the kingdom. The following table shows the rates of sickness and mortality of troops quartered in the large camps at Aldershot, Colchester, Shorncliffe, the Curragh, &c., as compared with those of troops stationed in thirty-seven large towns:—

1893.	Average annual strength.	Ratio per 1000 of mean strength.		
		Admissions.	Deaths.	Constantly sick.
Camps	24,733	783.0	3.92	48.32
Towns	53,282	802.2	5.36	48.26

At p. 13 there is a table showing the vital statistics of each arm of the service, in which the relatively high admission, invaliding, and constantly-sick rates of the Foot Guards are apparent.

There is not much to detain us in the sanitary reports of the home stations. The principal medical officer, Aldershot, considers that the occurrence of enteric fever at that camp was connected with faulty drainage, more especially in the North Camp, where several of the cases appear to have been due to sewer air, and the insanitary state of some of the huts. These huts are stated to be fast disappearing, and with this and the remodelling of the whole system of drainage consequent on the completion of the new brick barracks and married quarters it is hoped that local insanitary causes will be removed. The new Tournay barracks are, it seems, temporarily used as a hospital pending the construction of the new one that has been authorised. The medical officers' quarters in these lines have, it is stated, been condemned, and the present sewage farm is to be closed and a new one at a greater distance from the camp is to be provided. The drainage of Wellington lines was being completely reconstructed. *En passant* we may remark that the coir mattresses in use are stated to have been unfavourably reported on, as they are more difficult to clean than the straw palliasses. There is one subject alluded to in some of the sanitary reports which we regard as highly important for the health and comfort of the soldier—viz., the provision of rooms for drying his clothing when saturated with wet, as it often is; and we think, too, that there should be a sufficient supply of hot water for baths and ablution rooms in barracks and camps to enable soldiers to have a warm bath periodically during the cold weather. It is not at all likely that soldiers will use the kind of baths provided at present during such Arctic weather as we have recently had, for example.

Turning to the health of the troops serving in the Mediterranean, there is not much to be said. The results as regards Gibraltar, where the average strength was 4743, are satisfactory; the mortality was only 2.74 per 1000, which shows a decrease on the average for the previous ten years, although the admission and constantly-sick rates were somewhat higher in 1893. Whenever a case of enteric fever occurs the system uniformly adopted is for the medical officer in charge of the barracks, in conjunction with an officer of the Royal Engineers, to endeavour to trace out its cause. The great sanitary problems in Gibraltar are the prevention and mitigation of the overcrowding of a dense population, the provision of a good and adequate water-supply, and an improved system of drainage. The project of constructing a sewage outfall on the eastern beach, the principal medical officer tells us, has been abandoned, and a new scheme, with outfall at Europa Point, is likely to be adopted. A large non-dieted hospital has been opened at the Town Range Barracks. The disinfection of clothing and bedding is carried out by the Colonial authorities under a fixed scale of charges, and there is no doubt that this is by far the simplest and most economical method of procedure for the troops wherever the means are already available.

Malta with an average strength of 7161, had a death-rate during 1893 of 10.47 per 1000. An outbreak of enteric fever took place at Pembroke Camp chiefly among the men of the 1st Gloucestershire Regiment, recently arrived from England. A commission reported, after careful investigation, that the outbreak was attributed to contaminated water. There were 171 admissions for ague, 121 for remittent fever, and 2 for malarial cachexia, but no deaths. Ague is not a disease of Malta, and the prevalence of this fever in the command was attributable to the arrival of a regiment from Mauritius and troops from India, who brought the disease with them. During the summer months halt the troops, we are told, sleep under canvas—an excellent practice, which would do no harm if extended to all of them. Cyprus, which is now given up as a military station, was healthy, and has always proved so during our occupation of it, except at first, when the great sickness was mainly attributable to the exceptional character of the season, and still more to our own want of care and forethought in making proper provision.

Passing over Canada, the West Indies, and Western and South Africa, we come to the Mauritius, where the average strength of the garrison was happily small (551), for it is a most malarious and unhealthy station, especially as far as Port Louis is concerned. Malarial fevers, which have been for many years past very prevalent, gave rise in 1893 to no less than 607 admissions and 5 deaths, giving ratios of 110.6 per 1000 admissions and 9.07 deaths. Of the 607 admissions, 447 were cases of remittent fever and 160 cases of ague. There were 82 invalids sent home during the year, amounting to 148.82 per 1000 of strength; of these, however,

TWENTY-THIRD
APPENDIX

(1893.)
more the rate of
ing a malarious
or 1893, and it is
a mark that the
of the year.

only 15, or 27.22 per 1000, were finally discharged. The greatly increased prevalence of malarial fever in 1893 is attributed to the severe rainfall and mass of vegetable debris washed down by the hurricane in the preceding year. There is probably no place that affords better opportunities for the study of the relation of Laveran's parasite to malarial fever than the Mauritius, and we trust that we shall be furnished later with the results of the examination of the blood of patients exhibiting the phenomena of these fevers. The pathological cause should be determined beyond all doubt, and it should also be ascertained whether the cyclical growth and development of the parasite correspond with the cyclical periodicity of the fever, and whether the appearance of the young *anetæ* in the corpuscles and that of their sporulation correspond with the apyrexial and fever accession periods of the disease.

A considerable part of the report is, of course, devoted to the health statistics and sanitary state of the European troops in India. The prevalence of venereal diseases and the grave amount of inefficiency to which they give rise, as well as the prevalence of enteric fever among our troops moving in India, naturally receive a good deal of attention.

The average strength of the warrant officers, non-commissioned officers, and men in India for 1893 was 69,865; the admissions into hospital were 98,983; and the deaths 919, of which 881 took place in India, and 38 (being those of invalids) on the passage to or after arrival in England. The rates of sickness for each of the three commands is shown in the following table:—

	Ratio per 1000 of mean strength.			
	Admitted.	Died.	Invalided home.	Constantly sick.
Bengal	1468.4	14.95	26.07	90.63
Madras	1232.2	9.81	26.22	85.01
Bombay	1434.8	10.73	22.04	75.34
Total	1416.8	13.15	25.32	86.60
Ten years, 1883-1892.	1448.3	15.21	25.51	76.22

The section of the report devoted to Egypt is interesting. The general health of the troops in this command during the year was not very satisfactory and compares unfavourable with that of the previous year. There was a slight decrease in the death-rate, but the sick-rates are increased, more especially at Cairo. The greater part of the troops had only arrived in the country during the year. The sanitary state of the barracks and hospitals was well attended to and satisfactory, which cannot be said, however, of places outside them in their vicinity.

We have only a very brief space left for the papers in the appendix to the report. That on the progress of hygiene is well worth reading, as it briefly summarises the chief points which have attracted attention during the year and furnishes the reader with a good deal of useful information concisely stated; and the report on the Congress at Budapest also contains a large amount of valuable material, not only about the congress, but about the systems of water-supply and sewage disposal &c. of various places which the Professor of Military Hygiene visited *en route*. Brigade-Surgeon-Lieutenant-Colonel Stevenson, Professor of Military Surgery, and Surgeon-Major Whitehead, the Assistant Professor, contribute an excellent paper on the operations performed at the Royal Victoria Hospital, Netley, during 1894, accompanied with a description of, and comments upon, the more interesting and striking cases. Surgeon-Lieutenant-Colonel W. S. Pratt, gives a good and instructive report of the Eighth Congress of the Association Française de Chirurgie, held at Lyons in September last, with a set of diagrams. Surgeon-Major James, contributes a very full and elaborate report, illustrated by diagrams, of the late epidemic of bubonic plague at Hong-Kong, which seems to have been very carefully and well prepared; and the volume contains, in addition, several papers of surgical interest by other members of the Army Medical Staff.

VACCINATION GRANT.—Mr. James T. T. Ramsay, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., public vaccinator for Witton and Livsey, Blackburn Union, has been awarded the Government grant for three years' efficient vaccination.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6678 births and 6683 deaths were registered during the week ending March 2nd. The annual rate of mortality in these towns, which had increased in the five preceding weeks from 18.7 to 29.6 per 1000, further rose last week to 32.9. In London the rate was as high as 38.5 per 1000, while it averaged 28.9 in the thirty-two provincial towns. The lowest rates in these towns were 15.1 in Derby, 16.1 in Norwich, 17.0 in Sunderland, 18.5 in Gateshead, and 19.1 in Leicester; the highest rates were 38.5 in London, 39.2 in Plymouth, 43.4 in Halifax, 49.2 in Nottingham, and 55.5 in Liverpool. The 6633 deaths included 330 which were referred to the principal zymotic diseases, against 316 and 317 in the two preceding weeks; of these, 113 resulted from whooping-cough, 67 from measles, 47 from diphtheria, 36 from diarrhoea, 35 from "fever" (principally enteric), 30 from scarlet fever, and 2 from small-pox. No fatal case of any of these diseases occurred last week in Swansea, Derby, or Huddersfield; in the other towns they caused the lowest death-rates in Hull, Bristol, and Bradford; and the highest rates in Liverpool, Manchester, Bolton, Salford, and Brighton. The greatest mortality from measles occurred in Plymouth, Bolton, Preston, and Sheffield; from whooping-cough in Brighton, Cardiff, Birkenhead, Manchester, and Halifax; and from "fever" in Salford. The mortality from scarlet fever showed no marked excess in any of the large towns. The 47 deaths from diphtheria included 31 in London and 2 each in West Ham, Birmingham, Manchester, Salford, and Oldham. One fatal case of small-pox was registered in London and 1 in Liverpool, but not one in any other of the thirty-three large towns. There were 68 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 2nd inst., against 56, 67, and 75 at the end of the three preceding weeks; 8 new cases were admitted during the week, against 18, 18, and 19 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1621, against 1667, 1657, and 1653 on the three preceding Saturdays; 143 new cases were admitted during the week, against 149, 159, and 152 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 430, 840, and 1120 in the three preceding weeks, further rose to 1449 last week, and exceeded by as many as 945 the corrected average. The causes of 122, or 1.8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Bolton, Oldham, Bradford, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the four preceding weeks from 23.9 to 41.1 per 1000, further rose to 42.8 during the week ending March 2nd, and was 9.9 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 24.9 in Aberdeen and 26.0 in Greenock to 39.1 in Leith and 53.6 in Glasgow. The 1236 deaths in these towns included 51 which were referred to measles, 30 to whooping-cough, 10 to scarlet fever, 9 to diarrhoea, 8 to "fever," 5 to diphtheria, and 2 to small-pox. In all, 115 deaths resulted from these principal zymotic diseases, against 115 and 118 in the two preceding weeks. These 115 deaths were equal to an annual rate of 4.0 per 1000, which was 2.4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 26 to 54 in the three preceding weeks, were 51 last week, of which 21 occurred in Edinburgh, 15 in Glasgow, and 13 in Aberdeen. The 30 deaths referred to whooping-cough were within 6 of the number in the preceding week, and included 18 in Glasgow and 4 in Leith. The fatal cases of scarlet fever, which had been 6 and 4 in the two preceding weeks, rose again to 10 last week, of which 4 occurred in Glasgow and three in Edinburgh. The 8 deaths referred to different forms of

"fever" exceeded those recorded in any recent week, and included 2 each in Edinburgh, Dundee, and Paisley. The fatal cases of diphtheria, which had been 6 and 7 in the two preceding weeks, declined to 5 last week, of which 3 occurred in Glasgow. The 2 deaths from small-pox were recorded in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 214, 345, and 517 in the three preceding weeks, further rose to 544 last week, and exceeded by as many as 426 the number in the corresponding week of last year. The causes of 111, or 9 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 31.9 to 35.1 per 1000, declined again to 32.7 during the week ending March 2nd. During the past nine weeks of the current quarter the death-rate in the city has averaged 33.0 per 1000, against 24.0 in London and 26.8 in Edinburgh. The 219 deaths registered in Dublin during the week under notice showed a decline of 16 from the number in the previous week, and included 6 which were referred to the principal zymotic diseases, against numbers declining from 19 to 10 in the three preceding weeks; of these, 4 resulted from small-pox, 1 from whooping-cough, and 1 from "fever," but not one either from measles, scarlet fever, or diphtheria. These 6 deaths were equal to an annual rate of 0.9 per 1000, the zymotic death-rate during the same period being 1.5 in London and 5.9 in Edinburgh. The fatal cases of small-pox, which had been 8 and 6 in the two preceding weeks, further declined to 4 last week, a smaller number than in any week since November last. The mortality from whooping-cough and "fever" corresponded with that recorded in the preceding week. The 219 deaths in Dublin last week included 40 of infants under one year of age and 66 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a slight decline from the numbers in the preceding week. Nine inquest cases and 5 deaths from violence were registered; and 69, or nearly a third, of the deaths occurred in public institutions. The causes of 17, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

Surgeon-Captain James Rocheid Forrest from half-pay, to be Surgeon-Captain, vice J. G. Deacon, M.D., retired.

INDIA AND THE INDIAN MEDICAL SERVICE.

The *London Gazette* announces the Queen's approval of the following admissions to Her Majesty's Indian Medical Service: To be Surgeon-Lieutenants: *Bengal*: Charles John Milne; Algernon Francis Stevens; Clement Henry Bensley; Francis Hammond Watling; John Duncan McMillan; Arthur Gwyther; Edgar John Morgan; Alfred Edward Joseph Ward; William Carr; John Archibald Hamilton. *Madras*: Frank Wall; Charles Montague Mathew. *Bombay*: Samuel Evans; James Haldane McDonald. The services of Surgeon-Captain W. Vost, M.B., C.M., I.M.S. (Bengal), are placed permanently at the disposal of the Government of the North West Provinces and Oudh. Surgeon-Captain C. H. Bedford, M.D., I.M.S., Bengal Establishment, is appointed to be Medical Officer, Lawrence Military Asylum, Sanawar, vice Surgeon-Lieutenant H. M. Earle, who has vacated.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon John Stephen Dobbins, M.D., has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. The undermentioned Surgeons have been promoted to the rank of Staff-Surgeon in Her Majesty's Fleet:—Timothy Joseph Crowley, M.D.; Baskett Charles Edward Fitzgerald Gunn; Donald Templeton Heskyn, M.B.; John Evans Penn; Robert Howard Nicholson; John Leslie Barrington.

The following appointments are notified:—Fleet-Surgeons: R. Grant to the *Crescent* and R. D. White to the R. M. Division, Portsmouth. Surgeons: G. G. Barrett to the *Pembroke*; E. E. P. Tindall to the *Hamble*; K. C. Munday to the *Defiance*; H. W. G. Doyne and J. B. Jameson to the *Crescent*; A. G. Willey to the R. M. Depot, Walmer; C. H.

Upham to the *Virid*, for Plymouth Hospital; and W. Bowden, D.S.O., to the R. M. Division.

VOLUNTEERS.

Rifle: 1st Volunteer Battalion, the King's Own (Royal Lancaster Regiment): Richard Oxley Bowman, M.D., to be Surgeon-Lieutenant. 1st (City of Bristol) Volunteer Battalion, the Gloucestershire Regiment: James Young, M.D., to be Surgeon-Lieutenant. 2nd Volunteer Battalion, the Duke of Cambridge's Own (Middlesex Regiment): Surgeon-Lieutenant H. G. G. Wilkins, to be Surgeon-Captain. 9th Lanarkshire: Charles Symington, M.B., to be Surgeon-Lieutenant. 1st Dambartonshire: Surgeon-Captain J. McLachlan, M.B., resigns his commission. 1st Cadet Battalion, the Buffs (East Kent Regiment): Charles Walter Scott, M.B., to be Acting Surgeon.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned Officers of the Volunteer Force. *North-Western District: Engineers*: 2nd Lancashire (the St. Helens) Volunteer Engineers: Surgeon-Lieutenant-Colonel Egerton Francis Hall, M.D. 2nd Cheshire (Railway) Volunteer Engineers: Surgeon-Lieutenant-Colonel James Atkinson. *Southern District: Rifle*: 1st Wiltshire Volunteer Rifle Corps: Surgeon-Major (ranking as Lieutenant-Colonel) George Christopher Tayler, M.D., retired. *Scottish District*: 4th Volunteer Battalion, the Cameronians (Scottish Rifles): Surgeon-Major Johnstone Macfie, M.D.

DEATHS IN THE SERVICES.

Deputy Inspector-General Lyall, R.N.

By the death of Dr. David Lyall, Deputy Inspector-General of Hospitals and Fleets, at Cheltenham on the 25th ult., at the age of seventy-seven, the naval medical service has lost an officer of scientific attainments and reputation. The deceased officer entered the navy in 1839, after having passed the Royal College of Surgeons, Edinburgh, and taken the M.D. degree of the University (King's College) of Aberdeen, and was soon appointed assistant surgeon and botanist of the Antarctic Expedition under Sir James Ross. He was also surgeon and naturalist in the Arctic Expedition under Sir E. Belcher in 1852-54, for which he had the medal, and subsequently served in the Baltic campaign in 1855 (medal). Dr. Lyall was a Fellow of the Linnean Society. He was in due course appointed Fleet Surgeon, and in 1873 Deputy Inspector-General of Hospitals and Fleets, when he was placed on the retired list. In 1884 he was awarded a Greenwich Hospital pension.

Surgeon-General Clarke, I.M.S.

We regret to announce the death of Surgeon-General J. J. Clarke, Bengal Medical Service (retired list), on Feb. 23rd last, whilst on a visit at Leura, Toorak, Melbourne. The deceased officer entered the Indian Medical Service in 1853, and retired with the rank of surgeon-general in 1884, after a distinguished military career during the Indian Mutiny, throughout the whole of which he had served with the force under Generals Havelock, Outram, and Neill. He was with the Artillery and attached to the battery commanded by Sir William Olpherts, V.C., which won great distinction for its services. The late Surgeon-General Clarke was present at numerous actions, the relief and defence of Lucknow, the engagements under Sir James Outram and Lord Clyde, and rendered gallant services at Mungulwar, at Alumbagh, and at the Motee Mahal; he also served as principal medical officer in the Akha Expedition and was mentioned in despatches. In 1882 he was awarded a good service pension.

Surgeon-Major-General Thomas Rudd.

Surgeon-Major-General Thomas Rudd, M.D. Edin., died at San Remo on Feb. 24th. He served with the 8th Hussars during the Indian Mutiny in 1857-58, and was present at the capture of Kotah and at the battles of Kotaria and Khooshana (medal with clasp). He also served in the Afghan War of 1878-80 (medal).

PROPOSED TESTIMONIAL TO SURGEON-GENERAL SIR JOSEPH FAYRER, K.C.S.I., Q.H.P., M.D. EDIN., F.R.S.

As we have already announced, a movement is on foot to present a testimonial to Sir Joseph Fayrer on his retirement as Physician to the Indian Council, President of the Indian Medical Board, and Member of the Senate of the Army Medical School. The testimonial is to take the form of a portrait to be painted by an eminent artist, to be placed in the officers' mess at Netley, with a replica for Lady Fayrer. Should the fund permit, a reproduction of the portrait will

be sent to each subscriber. Subscriptions, limited to 10s. 6d., may be sent to Surgeon-Captain W. W. Webb, M.D., the honorary secretary, at Odstock, Netley Abbey, Hants.

THE OPIUM COMMISSION.

The report of this Commission will soon be in circulation. Its publication is no doubt anxiously awaited in India, as the subject is one gravely affecting the social life, habits, and customs of the native population and the finances of that country. Meanwhile, it must be very satisfactory to the Government of India to have the assurance of the Chancellor of the Exchequer that the cost of the Commission is to be borne by the English and not by the Indian revenue. We think that most people will concur in the justice and expediency of this decision.

THE ARMY MEDICAL STAFF IN INDIA.

In future medical officers proceeding to India will receive intimation of the command to which they will be posted for service in that country. It will be remembered that some time ago it was a subject of complaint that they were put to inconvenience by not knowing the presidency in which they would have to serve. This has now been rectified by the Secretary of State for War and India Office.

THE ARMY ESTIMATES.

The Navy and Army Estimates for the year have just been issued. We hope to be able next week to give a brief statement of these estimates as regards the medical services.

INFLUENZA AT ALDERSHOT.

The troops at Aldershot, as might have been expected, have not escaped the prevailing epidemic. A large number of sufferers from influenza have been under treatment as well as cases of disease of the respiratory system.

The hired transport *Victoria* arrived at Portsmouth on the 27th ult. She brought home 300 patients for the Royal Victoria Hospital, Netley.

Correspondence.

"Audi alteram partem."

THE UNIVERSITY OF CAMBRIDGE AND THE EXTENSION OF SCIENCE TEACHING.

To the Editors of THE LANCET.

SIRS.—May I call attention to an advertisement, which appears in the columns of THE LANCET of this date, of an invitation to qualified medical men to come up to Cambridge for a course of demonstrations and lectures. It seems to us there must be many men resident out of reach of large schools who would derive much advantage from seeing the work done in our laboratories and hearing what is going on in modern medicine and the ancillary sciences. The fees, including board and lodging (probably in college), are fixed as low as possible. The University professors have generously offered their services, and will open their laboratories for the demonstrations, and some cases of special clinical interest will be shown by members of the honorary staff of the hospital. It will not be possible, of course, to arrange for private workers on such an occasion, but if the opportunity seems to be valued we hope to repeat the invitation in future years, and perhaps to extend the time a little.

Believe me, Sirs, yours faithfully,

T. CLIFFORD ALLBUTT,

Regius Professor of Physic in the University of Cambridge.
Cambridge, March 5th, 1895.

P.S.—It is of great importance to us to receive early applications that we may know how to prepare for our visitors.

"THE TREATMENT OF INFLUENZA."

To the Editors of THE LANCET.

SIRS.—In THE LANCET of March 2nd Dr. Burney Yeo directs attention to the value of quinine in the treatment of influenza. May I venture to suggest that since quinine is not completely excreted from the tissues for some days, it is not necessary, in order to produce its specific effect, to give the

drug in such large doses as to produce cerebral symptoms? Three to five grains given in an effervescent draught every three or four hours markedly controls the course of the disease and rarely gives rise to "cinchonism." The large doses of quinine given on the continent in this disease appear to be quite unnecessary and not altogether devoid of danger, for I have seen fifteen grains given every three hours produce marked cardiac depression, particularly in elderly people. Thus, whilst quinine given in these comparatively small doses in the form of an effervescent saline draught undoubtedly in many cases exercises a controlling influence on the course of the disease, yet the pyrexia with its attendant symptoms may be but slightly relieved, and for this purpose three to five grains of phenacetine combined with a few grains of citrate of caffeine acts as a safe and efficient antipyretic and anodyne.

I am, Sirs, yours faithfully,

J. H. MARSH, M.R.C.S., L.R.C.P. LOND.

The Infirmary, Macclesfield, March 2nd, 1895.

To the Editors of THE LANCET.

SIRS.—I read with much interest Dr. Yeo's valuable letter on the Treatment of Influenza in last week's issue of THE LANCET, and should like to endorse what he says in reference to the deleterious effects of antipyrin in the treatment of this scourge. In comparing notes of the cases which have presented themselves for treatment during the past five years it has forcibly struck me that the mortality has been gradually diminishing, and the period of convalescence shortened in each successive epidemic. I do not consider this due to any lessened virulence of the much-maligned bacilli, but to the fact that antipyrin and similar depressants are being withheld in the treatment of this disease. During the first epidemic five years ago I noticed the great prominence given to pneumonia as a complication by all writers on influenza. My own firm conviction is, and has been all along, that the antipyrin treatment was entirely responsible in many cases for the onset of the pneumonia, and that ordinary cases of influenza with bronchitic trouble ended frequently in broncho-pneumonia when antipyrin was administered. During the past three epidemics I have not seen a single case of pneumonia complicating influenza excepting in asthenic cases in very old persons. So long as we have therapeutic agents such as quinine and alcohol we need not be afraid to combat this year's epidemic.—I am, Sirs, yours faithfully,

FRANCIS WILLIAM GRANT, M.D., B.Sc., C.M. Edin.

Elgin, March 4th, 1895.

"PROFESSOR W. R. SMITH AND THE MEDICAL SUPERINTENDENTS OF THE HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD."

To the Editors of THE LANCET.

SIRS.—My attention has been drawn to certain editorial remarks in THE LANCET of the 2nd inst. dealing with a report in the *Times* of a speech made by me as a member of the Metropolitan Asylums Board on Saturday, Feb. 2nd. I regret that you have considered it necessary to allude to the subject, but as your remarks may give an erroneous impression as to the facts of the case I shall be obliged by your kindly inserting this letter. In the first place it is true that I called upon you on Feb. 27th, and this to express my regret that I had not received your letter of Feb. 6th, and further to state that your letter dated Feb. 21st I had only received that morning, consequently I had not been able to reply to them. I think these facts should have been mentioned, as otherwise some discourtesy on my part would be inferred. The main point at issue cannot I think be properly appreciated unless considered in the light of a knowledge of the action of the Metropolitan Asylums Board relative to the diagnosis and treatment of diphtheria, in which I have taken a somewhat prominent part. The managers have made arrangements by which a bacteriological examination shall be made of all cases of diphtheria, both upon their admission and before their discharge from their hospitals, and in addition—with the object of providing a proper supply of antitoxic serum—have placed stabling &c. at the disposal of the director of the Research Laboratories of the Royal

Colleges of Physicians and Surgeons consequent upon an arrangement made between the Asylums Board and the committee of management of the Laboratories. Further, to ensure that proper statistical information should be forthcoming at the proper time, the medical superintendents of the hospitals and the director of the Research Laboratories of the Royal Colleges were requested to submit a form upon which such records should be kept. This they did, and the same was approved by the subcommittee, to whom the whole matter has been referred. Throughout, as I think is known, great opposition has been shown to these projects, on the one hand by those who adopt the views of the Anti-Vivisection Society, and by others who wished the services of a particular institution to be engaged. In January notice was given of a motion relative to statistical returns on the subject of the antitoxic serum treatment by a gentleman who had throughout in this particular assumed an antagonistic position to the action of the Board; the motion came on for discussion on Feb. 2nd, and at the same time an amendment to the proposition of which I had given notice. Upon entering the council chamber my attention was at once drawn to THE LANCET, which published that day what purported to be a report from the director of the institution to which I have alluded, and which report embodied certain statistical returns in the form of reports from some of the hospitals of the Asylums Board. These returns had never been before the subcommittee before mentioned, and of which I am a member, nor had they been placed before the committees of the various hospitals concerned; in short, information which many members of the Board were most anxious to obtain could only be elicited from an official report of a body with which the Asylums Board had no connexion.

If I remember rightly, the words I used on Feb. 2nd were to the effect that I felt great regret that such information had been given, that in my judgment such action was not only most indiscreet but tended to give the impression of disloyalty to the Board. These words rightly express my feelings to-day. Of course, as must be obvious, every individual member of a board is responsible alone for any expression of opinion to which he may give utterance; but in this particular case it should now be known that at the first meeting of the General Purposes Committee after Feb. 2nd—a committee consisting of the whole of the members of the Board—it was unanimously decided to send a letter to the medical superintendents on the subject, and with their replies I think it would have been prudent to have allowed the matter to rest.

It is true, as you have rightly pointed out, that I myself fill certain public positions, and consequently I cannot be unmindful of the difficulties and responsibilities of others similarly placed; but in these positions I recognise a duty to the authorities I serve, and I at the same time do not ignore the fact that members of public bodies have duties to discharge, not alone to those who elect them, but also to themselves if they ever hope to exercise any proper influence.

I am, Sirs, yours faithfully,

WILLIAM R. SMITH.

The Metropolitan Asylums Board, Norfolk House,
Norfolk-street, W.C., March 6th, 1895.

To the Editors of THE LANCET.

SIRS,—The annotation under the above heading in THE LANCET of March 2nd has considerably surprised me, and I feel it demands some further comment, though, no doubt, the Times reporter is quite able to take care of himself. I can only say that Professor Smith must have a very short memory regarding his own speeches, for not only am I quite positive that he "censured" the action of some of the medical superintendents, but also that he did so in very measured language, and so much did it impress me that I rose in my place immediately after he had spoken and stated that I did not think these officers were deserving of censure by him, considering the circumstances under which they had given some information on antitoxin, not to the leading medical papers, as stated by Professor Smith, but, as I understood, to the superintendent of the British Institute of Preventive Medicine.

I am, Sirs, yours faithfully,

A. B. R. MYERS,
Brigade-Surgeon-Lieut.-Colonel; Manager,
Metropolitan Asylums Board.

March 2nd, 1895

THE STORAGE OF ANTITOXIN.

To the Editors of THE LANCET.

SIRS,—It seems to me that much unnecessary trouble is being taken in the storage and distribution of diphtheria antitoxin by the elaborate precautions which are required so long as it continues to retain its liquid form. I would suggest that in future the liquid antitoxin should, as soon as it has been obtained, be evaporated *in vacuo* over sulphuric acid and stored and distributed in the form of a dry powder, whose exact quantitative relationship to the liquid antitoxin or to the toxin itself could easily be ascertained and stated. There can be no doubt that in this dry form diphtheria and all other antitoxins will retain almost indefinitely their original effects. Were this plan adopted it would also be possible considerably to reduce the bulk of liquid injected under the skin.

I am, Sirs, yours faithfully,

Edinburgh, March 5th, 1895.

THOMAS R. FRASER.

THE TREATMENT OF MEMBRANOUS COLITIS.

To the Editors of THE LANCET.

SIRS,—In an interesting paper on Colitis, which appeared in THE LANCET of March 2nd, Dr. Hale White says, when considering the treatment of the membranous form of the disease: "It has been suggested that in a very intractable case it might be justifiable to open the colon high up." In June of last year I performed an inguinal colotomy in the right side on a patient who was passing large quantities of blood with membrane, one complete cast of the bowel being twenty-two inches in length. A month ago I closed the colotomy opening, and later propose to report the case in full. So far the success is complete.

I am, Sirs, your faithfully,

Charles-street, W., March 6th, 1895.

SKENE KEITH.

REPORTS OF THE MEDICAL OFFICERS OF HEALTH: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—Year by year are published valuable reports by the medical officers of health of the various urban and rural sanitary authorities. Many of these reports contain important information and suggestions, the result of practical experience, on the causation and prevention of disease, histories of epidemics, difficulties in carrying out sanitary laws or reforms, and interesting statistical returns. Much of this good work is lost to those interested in sanitary science owing to the difficulty of obtaining such reports, and the time that would be occupied in reading them. No doubt your valuable journal frequently gives extracts from the leading reports upon points under discussion, but I would suggest the publication yearly of a volume giving a *résumé* of all the reports of that year. Such a book would confer great benefit on medical officers of health and those interested in public health. It would form a sanitary history of the year, would show the sluggard what the advanced were doing, and would supply material for the advocates of sanitary reform. I need not go further to prove the practical use of such a publication. The information should be carefully condensed and classified, and advances in sanitary science abroad could be included. This compilation would involve considerable labour and expense, and could hardly be undertaken by a private publishing firm with any prospect of financial success. But as such a publication would be a public gain it might reasonably be brought out by the Local Government Board as a part of the sanitary administration of the country. That Board, too, has special sources of information which could be utilised.

I am, Sirs, yours faithfully,

ANTONY ROCHE, M.R.C.P.I.,

Professor of Hygiene, Catholic University; Examiner, Royal University of Ireland; Fellow of the Sanitary Institute, &c.
91, Stephen's-green South, Dublin, March 2nd, 1895.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

To the Editors of THE LANCET.

SIRS,—We are instructed by the council of the London and Counties Medical Protection Society to inform you that

the letter which appeared in the *Echo* of the 1st inst. under the heading of the "London and Counties Medical Protection Society," and signed "G. B. Mead," was wholly unauthorised by the council, and that in consequence of such letter Dr. G. B. Mead's connexion with the society has been determined.

We are, Sirs, your obedient servants,

LE BRASSEUR AND OAKLEY.

Solicitors for the London and Counties Medical Protection Society, Limited.

12, New Court, Lincoln's-inn, W.C., March 6th, 1895.

* * The following is the text of the letter referred to by Messrs. Le Brasseur and Oakley :—

To the Editor of the *Echo*.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

President: Jonathan Hutchinson, LL.D., F.R.S.

Treasurer: Dr. George A. Heron, F.R.C.P., 57, Harley-street, W.

Hon. Secs.: Dr. George B. Mead, L.R.C.P., Mentmore, Newmarket, Suffolk; Dr. Hugh Woods, B.A., 11, Archway-road, Highgate, N.

Financial Sec.: A. G. R. Foulerton, M.R.C.S., 22, Ovington-gardens, S.W.

Registered Offices: 12, New-court, Lincoln's-inn.

SIR,—It has often struck me what a good thing it would be if the medical profession had a sort of understanding with the editor of a paper like yours that its columns should be open to the discussion of medical questions of a medico-political or ethical character, and both the paper and profession would, I am sure, benefit thereby. The medical papers—*Lancet*, *Medical Times*, *Gazette*, *Press* &c.—all are crammed with cases, papers, and contributions of the most deadly-lively and useful character, to the exclusion of important and personal matters. More than half these so-called contributions are mere pulls of medical notoriety seeking to prey upon the rich public; a large proportion are simply a tissue of lies, and inserted by the editors knowing them to be lies, but being over or under well-known names are inserted. The principal portion of the medical press obtains its income from the sale of these precious papers and from the insertion of quack advertisements of preparations mostly useless and mostly of American origin.

I asked an American the other day if the medical and other papers of America were stuffed with advertisements of drugs, &c., of English origin. "Our people are not such fools as to swallow them," was the reply. If you entertain this idea I should be glad to discuss the matter with you personally.—Yours, &c., G. B. MEAD.

1, Oakley street, London, S.W., Feb. 27th.

We were perfectly aware that such a letter could not have been authorised by the society, although it was written apparently in the form of an official communication.—ED. L.

To the Editors of THE LANCET.

SIRS,—In consequence of Dr. Mead having ceased to be one of the honorary secretaries of this society, the council request that those having business with the society will kindly address all communications to Dr. Woods, honorary secretary, 11, Archway-road, Highgate, N., excepting communications relating to the payment of subscriptions, which should be addressed to Mr. A. G. R. Foulerton, 22, Ovington-gardens, S.W.—I am, Sirs, yours faithfully,

HUGH WOODS, Hon. Sec.

March 6th.

DUNKLEY v. LANGLEY.

To the Editors of THE LANCET.

SIRS,—A meeting of some of the medical friends was held here on Thursday to sympathise with Mr. Langley in the unjustifiable action brought against him by the plaintiff for neglect in an obstetric case in which the jury, without hearing all the evidence for the defence, returned a verdict that there was no neglect. A subscription was also started to help to recoup Mr. Langley for the heavy legal expense incurred in defending himself. As it is a case in which all medical men are liable to a similar action being brought against them, Dr. Shaw, of 10, St. Thomas's-street, S.E., will be happy to receive subscriptions, or they may be sent to me.

I remain, Sirs, your truly,

Surrey-square, March 6th, 1895.

W. RUMBOLL.

The following subscriptions have been received or promised for the Langley defence fund :—

	£	s.	d.		£	s.	d.
Mr. Collymore	Dr. Baldwin
Dr. Milson	Mr. Jacobson
Mr. Rumboll	Mr. Arlbutnot Lane
Dr. Shaw	Dr. McBride
Dr. Williams	Dr. F. Taylor
Dr. Wills				

"LIFE ASSURANCE SCHEMES."

To the Editors of THE LANCET.

SIRS—I am indebted to you for courtesy in allowing me to reply in your columns. May I once more trench upon your kindness for space in reference to your note added to my letter, whence it might be assumed that this office offers no other policy than the one to which you refer? The contrary is the fact. We seek to meet the wants of everyone—those who "want a round sum in hand" as well as those who, being unable to use the "round sum" advantageously, are better protected by an income for a given period, and then the "round sum in hand." The following instance is a striking comment on your remarks as to the value of a "round sum" in hand, and shows that it is not always "a priceless boon." We paid a claim of £2000 to a widow properly entitled. On leaving our office she met a friend, whom she told that she had just received a "round sum" and was desirous of making the best of it. The friend was ready to advise her. He had a good investment, and a certain income. She endorsed our cheque to him. The speculation was so unfortunate that she has never since received any interest and has lost the capital. Thus the care and forethought of the husband were nullified by the money being paid in full to the widow. Would not our debenture policy have proved better in this case? There are all kinds of cases to be met. The pride of this office is that it meets the wants of all, and is ready to facilitate a change from one method to another when changed circumstances render it desirable; and the very objection you make to our debenture policies is provided for in that very contract—e.g., suppose a man with a debenture policy finds that from different causes his estate would be better protected by payment of the full sum assured at death, a simple request to that effect and the office would very readily comply with his wishes and pay his representatives a round sum at his death. I hope you will absolve me from even the spirit of scolding; I only ventured to suggest with the meagre facts before you in relation to our debenture policy you did not quite grasp its provisions. For a man who simply wants temporary cover the debenture policy would not suit his requirements. I ventured to point out in my previous letter that even the scheme to which you alluded was not as cheap as what is known amongst all insurance companies as "term insurance" for those who merely wished temporary insurance.—Thanking you for your courtesy, I am, Sirs, yours truly,

D. C. HALDEMAN,

General Manager of the Mutual Life Insurance Company of New York.

March 5th, 1895.

"REMUNERATION OF RESIDENT OFFICERS AT ST. BARTHOLOMEW'S HOSPITAL."

To the Editors of THE LANCET.

SIRS,—Under the above heading you are permitting a discussion in your columns of what I have always regarded as my one grievance against St. Bartholomew's Hospital. The question is a perfectly simple one: Does the present system secure for the resident appointments the men most fitted to hold them—that is, does it always secure men likely to carry out their duties to the greatest advantage of the sick poor who seek relief at the hospital, and does it secure the men who are most likely to avail themselves of the opportunities for knowledge and skill which these appointments so abundantly afford, such experience being acquired for the future benefit of the public at large? To both these questions I answer emphatically, No. The best men may be, and not rarely are, excluded solely by reason of their poverty. I know of several instances directly to the point, but the question must be largely decided by statements of personal experience. I will state, therefore, that I am one who was excluded from resident appointment of St. Bartholomew's Hospital solely by reason of the *res angusta domi*; while, as evidence that my professional attainments were at any rate equal to those of some of the men who held the appointments, I may, under the veil of anonymity, state the fact that the examiners at the London University (of whom one was the most distinguished physician and teacher at the hospital in question) considered me to be sufficiently qualified in professional work to deserve a gold medal in medicine both at the M.D. and M.B. examinations, with first-class honours in both the other subjects of examination. Like many another, I had to

seek refuge in the provinces, where a comfortable emolument was added to opportunities for practical work perhaps not inferior to those at my *Alma Mater*. The strangest contribution to the discussion is that of the plutocratic "Old House Surgeon," who says that the post being a coveted and a valuable one, the wage is simply a question of supply and demand! Of course, if the intention of the hospital authorities is to make a profit out of these appointments, this is perfectly true and sound economy; but why not put them up to public auction and get the full market price? If, however, the intention is to get the men best fitted to superintend the care of the sick and most likely in later life to apply their opportunities of experience to the public good, then it is difficult to see how the longer purse helps to differentiate the fit from the unfit. Rather would it appear that the one is able to pay for the privilege of acquiring his experience, perhaps at the cost rather than to the advantage of those who seek for aid through the portals opened by R. here.

I am, Sirs, yours truly,

GOLD MEDALIST BUT NOT HOUSE PHYSICIAN.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Hospital for Consumption and Diseases of the Throat and Chest.

THE annual meeting was held on the 20th ult., and the financial statement was of a character only too common. The calls on the resources of the hospital were heavy, and the income was not sufficient to meet them. This is the only institution in Manchester where provision is made for the treatment of phthisical cases. The *Manchester Guardian* says: "If there is one district in England in which a charity of the kind has special claims on the practical sympathy of the benevolent it is that which includes Manchester." The deficit on the year amounts to £478 5s. 10d., and besides this there is a debit balance of £1098. Limitation of the work was foreshadowed as necessary unless the subscriptions were increased. This would lead to closing some of the wards of the in-patient hospital at Bowdon. It has forty-eight beds and is ten miles from the city, where the air is purer and the climate somewhat more genial than in Manchester. Last year 256 patients were admitted, and the average stay in hospital was sixty-six days. The hospital is well arranged, situated in its own grounds, and freely exposed to the sun; patients in the early stages almost invariably improve, sometimes most notably; and cases of arrested phthisis are not rare. The out-patient department is in Manchester, and last year 9373 cases attended, more than three times the number in 1884. The chairman, in calling attention to the critical financial condition of the institution, said he feared drastic steps would have to be taken to limit the scope of the work; but "he was sure nothing of the kind would be necessary if the public knew the good work the hospital was doing, and particularly in the case of young people, whom they tried to help when the disease was in its early stages."

The Children's Hospital.

The annual meeting of this important institution was held the other day, and the report showed that this popular and well-supported charity was to some extent feeling the pressure of hard times, and that £575 19s. 3d. were owing to the bankers. At the out-patient department 10,004 cases were treated, while 1164 were admitted to the hospital at Pendlebury. The medical report drew attention to some important points as to infant mortality. In Norway, in rural England, and among the well-to-do populations of our suburbs it averaged 100 per 1000 births, "while in Manchester it amounted to 203 per 1000; and if they took the infant mortality in some of the most congested districts, where poverty, drunkenness, and vice were the commonest, they would find death-rates amounting to 300 and even 500 per 1000. One of the most immediate and efficient causes was the substitution of artificial foods for the mothers' milk." Another was the quality of the milk supplied to our towns. "In many cases it was not merely stale but it came to them contaminated by farm-yard refuse and was swarming with more or less injurious organisms." The report goes on to say that the subject of infant life insurance had been carefully inquired into as it affected the out-patients, and that "of the 155 who died no

fewer than 105 were insured. The sum insured for was ascertained in 77 cases and amounted to £244 10s., or an average of £3 3s. 6d. per head. In two cases the sum was as high as £9. In 11 cases only was it stated that some part of the payment consisted of spirits or drink of some kind; but as 22 other children were insured in public-house clubs that were known to give drink in part payment of the claims there could be little doubt that such payment was made in all the 33 cases." And the report very properly goes on to say: "Whatever might be thought of the general question of child-life insurance, this special feature admitted of no defence."

Extension of the Royal Infirmary.

A special meeting of the trustees was held on the 26th ult. to consider this question. Dr. Renaud, the senior consulting physician, proposed a resolution embodying in the main the views of the board of management, of which he is an influential member, in favour of building two lateral extensions, not from the front of the building, as was contemplated in a former scheme, but from half-way down the sides. This would involve encroachment to a considerable extent on the open space round the infirmary, in contravention of the resolution of July, 1892, which said that no such encroachment should take place, and the retention of the somewhat antiquated and objectionable features of the present infirmary. An amendment was proposed to the effect that it was advisable that the increased accommodation required should be provided by the gradual rebuilding of the infirmary on the present site, and that plans should be prepared and submitted to a special meeting of trustees to be held within three months from that date. After considerable discussion the amendment was carried by a large majority, but the seconder of the resolution, on behalf of the board of management, demanded a poll. This does not seem wise on the part of the board, for if it went in favour of the scheme proposed by Dr. Renaud the feeling against covering any more of the ground is so strong that it would most probably have to be abandoned. The architectural effect would be bad, and the scheme is one of inartistic, inefficient patchwork. It is unfortunate also that the amendment requires plans to be so hastily provided by the board. The infirmary stands on the finest site in the city, and the plans for rebuilding, which in the end will be required, should be thrown open to competition under conditions which would lead the most eminent architects to compete. It is believed that almost the whole of the medical staff would prefer reconstruction on the present site, but one or two are in favour of an annex nearer to Owens College. In time that may be required, but at present the urgent need is that the infirmary should be made equal to the demands on it and worthy of its well-earned prestige.

Manchester and Salford Provident Dispensaries Association.

This is the central body with which all the various branches are associated, and its twentieth annual meeting was held on the 26th ult. From the report it appears that there are 22,464 members (the highest number yet recorded) on the books of the different branches, and that during the year £4043 had been received in subscriptions from the members. "The council again express their acknowledgment of the services which are so efficiently rendered by the medical staff at the various dispensaries," and they hope that any difficulties between the staff of any dispensary and the committee and council may be satisfactorily removed. Nothing appears in the newspaper report of the meeting about the resignation of the whole of the staff of the Pendleton branch, so it does not seem as if in that branch their differences had been adjusted. The chairman described the association as "an institution to give a little help to those who wanted help, and who did not want charity in the sense in which that misused word was generally applied"; and he held that it had greatly lessened the abuse of the out-patient department of the hospitals. He did not touch on the fact that the present working of these dispensaries had estranged the great body of general practitioners, who were at first generally favourable to them; nor did he mention the various departures made from the original scheme, such as the doing away with a wage limit and the admission of all comers, whatever their income; nor did he allude to the recent severance of the connexion between the provident dispensaries and the Infirmary, at the urgent representation of the medical staff, on account of the unfair advantages their members had over all other poor deserving persons. It is strange that the

gentlemen interested in this movement and affording it their patronage and support do not see that these dispensaries are really sweating agencies for obtaining cheap medical attendance for all who choose to join them at the cost of the general practitioner, and that their vicarious philanthropy consists in exploiting the same unhappy person.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Queen's Hospital.

THE annual meeting of the governors of this institution was held on Feb. 27th under the presidency of the Earl of Dudley. The meeting was a large and representative one, the interest of the occasion being the presentation to Mrs. Johnson of a replica of the portrait of her husband, Alderman G. J. Johnson, hung in the board-room of the hospital, in recognition of his services to the institution. The President alluded to the mention in the report of the nursing scheme originated three years ago, and congratulated the committee upon its success. Dr. Carter supported the resolution adopting the report, and stated that it was now nearly twenty years since he became connected with the hospital. In his time unprecedented progress had been made; they had to deal with 20 per cent. more in-patients, and the out-patient department had nearly doubled. The mortality was now 5 per cent., as against 14 per cent. in the earlier period of operative work; the nursing department was also a great benefit. Sir James Sawyer spoke in high terms of the progress made and on the efficiency of the duties performed by all the staff. Alderman Johnson sketched the advance made by the hospital since his first connexion with it thirty-two years ago, and in fitting terms acknowledged the honour done to him and the compliment paid to his wife by the presentation of his portrait. Mr. Burdett, in moving a vote of thanks to the chairman of the committee, laid stress upon the fact that the training of nurses, as it was understood and known in this country and in America at this day, originated in its present form in the Queen's Hospital, Birmingham.

The Countess of Warwick on Nursing.

At a meeting of the Warwick board of guardians held on Feb. 23rd the Countess of Warwick moved the following resolution: "That immediate steps be taken to provide a competent night nurse for the workhouse infirmary, and that it might be well for her to take one or two months' duty in turn with the head day nurse." At present she stated that the nursing at night was left in the hands of the paupers; the result was that the helpless and sick were left very much to the tender mercies of uninstructed inmates for the night—a very unsatisfactory state of things. She mentioned that she had recently visited the Birmingham workhouse infirmary, which was conducted like a hospital, with 1500 beds and splendid arrangements, and had studied the paper which the matron had read at the conference the previous week. The Mayoress of Leamington (Mrs. Thursfield) seconded the resolution. A long discussion followed, and ultimately the motion was carried, it being decided to advertise for a night nurse with a midwifery certificate at £30 a year and rations.

A Novel Excuse for Adulteration.

A milkman was recently summoned for selling milk unusually diluted with water. The excuse given was that the snow had fallen from some roof into his cans and so caused the additional water to be present. He failed to convince the magistrates of this ingenious defence and was duly fined.

Birmingham General Dispensary.

At the annual meeting of subscribers held on Feb. 27th the committee reported that the income in 1894, including a balance of £69 14s. 11d., amounted to £11,868 8s. 7d.; the expenditure was £11,469 18s. 5d. The total number of patients admitted by tickets was 32,097, showing a decrease of 1150; the average cost of patients was the same as in 1893—viz., 3s. 11½d. Of the cases and accidents treated without tickets there were 4471. The total number was 36,568. The Mayor, Alderman Fallows, was elected President, Dr. Rickards consulting physician, and Mr. Barling consulting surgeon. The various votes of thanks were passed.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Medico-Chirurgical Society.

THE third night of the discussion at this society was on Feb. 26th. The meeting was held in the Royal College of Physicians, as the hall in which the society usually meets was not available. Dr. G. A. Gibson opened the discussion, and confined his remarks to the treatment of cardiac pain. Dr. James gave expression to doubts he had on the treatment of cardiac cases. Dr. G. W. Balfour was given another opportunity of speaking, and dwelt upon the more general aspects of cardiac treatment. Professor Fraser replied, and expressed his gratification at the interest which the discussion had raised.

Health of Edinburgh.

The death-rate of Edinburgh is again high, reaching 34 per 1000, while in Leith it is over 39 per 1000 for the past week. Of the deaths 2 were from small-pox. The intimations included 9 cases of small-pox, 42 of scarlet fever, and 569 of measles. Influenza is still very prevalent, and while, as a general rule, it is comparatively mild, it has brought in its train pneumonia and bronchitis, and these are claiming their victims, especially amongst the aged.

Death of Professor Blackie.

By the death of Professor Blackie Edinburgh and the University, and, indeed, Scotland, have lost one of their most unique figures and most prominent personalities. He was as well known in medicine as in arts, and when he was in the active performance of his duties as Professor of Greek there was not a more generally known figure about the University than his. He is to be accorded a public funeral, and the University shuts its class-room doors for the day.

High Death-rate in Glasgow.

In the past fortnight the death-rate of the city has reached the highest point for many years: 54 per 1000 last week, and 51 per 1000 the week before, while the figures for the three preceding weeks were 43, 32, and 26. As a contrast, it may be noted that the rate in the week of 1894 corresponding to last week was only 19, and in 1893 it was 27. Dr. Russell ascribes this excessive mortality to the severity of the winter, diseases of the lungs being responsible for 40 per cent. of the total deaths, while zymotic diseases have diminished rather than otherwise. We have recently had exactly the climatic conditions which always increase the Glasgow death-rate enormously—namely, a temperature continuously below the freezing point, accompanied by a dense fog, which was only dispelled from time to time by a bitter east wind, the cold period also being preceded by a four-week period in which the temperature was rarely more than one or two degrees above freezing point. All past experience shows how such conditions tell on the public health of Glasgow. In the week ending Dec. 6th, 1894, the rate was 37·3; in the fortnight ending March 31st, 1893, it was 36; in December, 1892, it was 37·5; and in the week ending Jan. 29th, 1881, after conditions exactly like those recently experienced, it was 46. But to appreciate the possibilities of a continuous frost and fog in Glasgow the winter of 1874-75 must be quoted: in the week ending Jan. 9th, 1875, being the seventh week of frost and fog, the mortality rose to 67. In such circumstances ordinary sanitary measures fail to touch the cause of public suffering; these can be dealt with only by such benefactions as are now being so freely and judiciously distributed by the Lord Provost's relief organisation, the funds at the disposal of which now reach about £10,000. The only possible palliative is warmth—the warmth of food, fire, and clothing. Small-pox continues to spread, though slowly, there being now 43 cases in hospital.

Aberdeen Royal Lunatic Asylum.

The mason work of the new hospital has been finished and the whole of the different blocks and corridors roofed and made watertight, while the plaster work is completed except a small portion. The buildings will be occupied by October next. The new hospital will accommodate 150 patients. The extreme length east and west is 526 ft. The administrative block, to serve the whole institution, occupies the central position; the other blocks extend symmetrically on the two sides—the female department on the east, and the male on the west—all connected by an amply lighted and ventilated corridor running from end to end of the

buildings, and opening into the central common dining hall. On each side of the administrative block is a department for the reception of cases of a recent hopeful variety—in other words, a mental observation block—each connected with the central by: (1) the main corridor in the rear; and (2) an exercise corridor in front—the space between the two being occupied by a glass-roofed conservatory for the recreation of the inmates in cold or wet weather. Beyond the observation block, and connected with it by the general corridor, is a hospital block at each end for the reception of sick from all parts of the institution. These are each furnished with a small kitchen for special needs. Beyond each hospital block, and disconnected from it, is a small block for the isolation of infectious disease. In the rear of the administrative block stands the block for heating and ventilation on the mechanical propulsion system by the Sturtevant Engineering Company. The lighting is to be solely electrical. The administrative block is three storeys in height, the mental observation blocks two storeys, and the hospital blocks one storey. The bath-room and lavatory accommodation is mostly contained in annexes to the main buildings. All the external walls are of granite. The engineering department will be contracted for forthwith.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Mr. Charles H. Robinson, F.R.C.S. Irel.

MR. CHARLES H. ROBINSON of Kingstown died on Friday, March 1st, after but two days' illness. He had been an examiner in anatomy, physiology, materia medica, and botany at the Royal College of Surgeons in Ireland; and a lecturer on several of these subjects in the Ledwich School of Medicine, Dublin. He had been for many years one of our special correspondents in Ireland, and was deeply and universally respected.

The Battle of the Clubs at Cork.

How will the dispute between the Cork medical men and the clubs end? This is a question asked by many people. My answer is that the medical men need only preserve their present passive yet determined attitude and the gradual disintegration of the clubs must result. Many indications point in that direction. I know one practitioner who last week attended three or four club patients, and each patient represented a different club. I could quote several instances of the same kind, and, what is more remarkable still, some of the most pugnacious members of the clubs have acted similarly. The wives of members in many instances decline to be treated by any but their previous medical advisers, and those members will soon commence to ask themselves whether it is wise for them to continue to contribute to clubs from which they derive no immediate benefit. So the very existence of many of the clubs is threatened, and the members have only their own perverseness to blame. The following subscriptions are announced by Mr. D. D. Donovan, the hon. treasurer of the Cork Society Medical Officers' Indemnity Fund:—Surgeon-Lieutenant-Colonel McCreery (Isle of Wight) £2 2s.; Dr. Oakshott (Cork), £3 3s.; Surgeon Foott, R.N. (H.M.S. *Lapping*), £1; Dr. John B. Isaac (Broadmoor Asylum), £2 2s.; and Dr. H. Macnaughton Jones (London), £3 3s.

Death of the Professor of Modern Languages in the Queen's College, Cork.

The Queen's College has sustained a great loss by the death of Professor Owen O'Ryan, who for a number of years with much distinction occupied the chair of Modern Languages. He was originally a student of the college, and afterwards resided for a considerable time in Germany, France, and Italy. He gained an intimate knowledge of the languages of those countries, and when the death of M. De Vericour created a vacancy the Government of the day unhesitatingly appointed Professor O'Ryan to the chair of Modern Languages. He afterwards became an Examining Fellow of the Royal University of Ireland, and was always most courteous and conscientious in the discharge of his duties. About two years ago incipient hemiplegia set in and some time later a severe attack of influenza caused the paralytic symptoms to develop more rapidly. He had twelve months' leave of absence from the college and the long-expected end came last Friday week. The many medical students who passed

through his class at the college or were examined by him at the University will hear of his death with unfeigned feelings of regret.

Some months ago a bazaar on a gigantic scale was organised for the purpose of procuring funds for the building of a new ophthalmic hospital. The committee of the bazaar met last week and announced that after defraying all expenses they had in hand the handsome sum of £4000.

March 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The late M. Alphonse Guérin.

THERE has just disappeared, in the person of Alphonse Guérin, one of the most prominent representatives of the old French school of surgery. Born on Aug. 9th, 1817, at Ploermel, in Brittany, he, at the early age of seventeen, embraced a medical career, much against his own wish, which inclined towards the profession of arms. It came about in this way. One of his cousins, a sister of charity at the Hospital of Bourbon-Vendée, wrote to his mother, a poor widow, offering to bring up Alphonse as a medical man. Yielding to the solicitations of his mother, he had no sooner reached the hospital than he had to assist at the gruesome operation of phlebotomy, performed by his relative, the sister of charity. The embryo surgeon promptly fainted away, but next morning he had to repeat the operation on the person of his teacher. He missed the vein, whereon his petticoated mentor and patient calmly remarked, "C'est ce qu'on appelle une saignée blanche; recommence de ce côté," offering the other arm. The blood flowed, and his cousin said, "Tu sais faire une saignée; tu peux être médecin." Other venesections and minor operations successfully performed imparted confidence to the beginner, and he then entered on that career of tenacious labour for which he was ever after renowned. Removed to Paris, we find him an "interne des hôpitaux" in 1840, "aide d'anatomie" in 1843, M.D. in 1847, "prosecteur des hôpitaux" the succeeding year, and "chirurgien des hôpitaux" in 1850. Like the late Dr. Dujardin-Beaumetz, his attempts to join the professorial staff of the Faculty ended in failure, the disappointment being due entirely to his uncourtier-like honesty of purpose and not to incapacity. His first wards were at Louraine Hospital in 1857. In 1862 he was transferred to Cochin, and in 1863 to St. Louis, where he remained for nine years, when he became attached to the Hôtel Dieu. Here his hospital career expired in 1879, he having attained the age limit for retirement. Elected a Member of the Academy of Medicine in 1868, he became President of that society in 1884, after having already filled the same dignified position at the Société de Chirurgie. At his death he was a Commander of the Legion of Honour. There was one other honour he coveted and never obtained, and that was a *fauteuil* at the Institut. And yet, who among his colleagues merited it more? His contributions to surgical progress were numerous and important, comprising as they do two works on diseases of women and one on operative surgery, which was in its day held in great esteem by a previous generation of students. But his chief title to fame is based on his advocacy of the *pansement ouaté* (cotton-wool dressings). As Professor Terrier remarked in his introductory lecture in 1893, the researches which led to the devising of this form of wound dressing marked an epoch in surgery intermediate between the old ideas and Listerism. As Professor Terrier says, it is the *pansement ouaté*, improved by modern discoveries, which will be the best practical method of treating wounds in the next big war. In 1870, while soldiers operated on by others died like flies, it was remarked that Guérin's patients recovered, thanks to the application of his method, in the invention of which he was inspired by the following considerations. The great desideratum in wound dressing was the filtering of the air from its contained germs, the maintenance of a uniform temperature and of a certain degree of elastic compression, and perfect rest of the wound secured by infrequent dressings. Alphonse Guérin very ingeniously applied wool for this purpose, and that his ideas are still in favour is shown by the large and universal use made of his method in combination with Listerism in the treatment of wounds in the Paris hospitals. We may therefore willingly accord to Alphonse Guérin the credit of having been a pioneer in surgical methods, and as such he is and will continue to be

honoured in his own country, if not out of it. As a man he was distinguished by a rigid sense of duty. Although on the honorary staff of hospital surgeons for the last fifteen years, he sat only a fortnight before his death as President of the Board of Examiners at the examinations for the place of *Interne*. He was also to have presided over the deliberations of the next French Surgical Congress. It will be remembered that he was vice-president of the last gathering held in October, 1894, at Lyons. Dr. Laborde has said of him: "Franche et loyale nature, d'une grande finesse d'esprit, maniant comme pas un le trait sarcastique qui parfois emportait le lambeau; mais au fond plein de cœur, de bonhomie, et de bonté, Guérin eût dû certainement avoir sa place à l'Institut si cette attribution n'eût dépendu et ne dépendait que de la justice distributive," which says much to the credit of Guérin and little to that of the body from which he was excluded. Fortunately, his claim to gratitude on the part of humanity will not be diminished by his failure to obtain an ephemeral honour of that kind. A Breton bretonnant (a Breton of Bretons), his purse was ever open to his needy compatriots, and he died full of love for his native department, where now lie his remains.

Drugs contraindicated during Pregnancy.

This very debatable question is settled in the following sense by M. Huguenin.¹ At the head of dangerous substances for the pregnant woman he places sodium salicylate, ergot of rye, salicylic acid, and salol. Then come purgatives. He cannot regard antipyrin and cocaine as inoffensive. But is it not possible to pronounce too absolutely on this point? Surely there are pregnant women and pregnant women. *Après* of the employment of drugs at this period of the woman's life, I have often thought that an authoritative statement regarding the drugs dangerous to the child when given to the nursing mother would be found useful. No practitioner would, I imagine, be content to combat syphilis in the child by prescribing mercury to the mother.

March 5th.

THE INDIAN MEDICAL CONGRESS.

PROCEEDINGS IN SECTION.

MEDICO-LEGAL MEDICINE.

DEC. 26TH, 1894.

The following are abstracts of papers read in the Section of Medico-Legal Medicine:—

On Some Cases of Poisoning by Scopolia Lurida.

Surgeon-Captain ALLAN MACNAB L.R.C.P. Lond., read a paper on Some Cases of Poisoning by *Scopolia Lurida*, in which he said:—

"Believing that few, if any, cases of poisoning due to this plant have yet been recorded, and in view of the possibility of an occurrence of the same kind as that which I am about to relate under similar circumstances, I am led to think it worth while to give the following account of an incident that occurred during the Black Mountain campaign of 1891 and to furnish a description from notes made at the time of a series of serious symptoms that rapidly supervened after the leaves and succulent stalks of *scopolia lurida* had been eaten in mistake for a very similar and quite harmless plant known to Ghoorkas as 'tambaku sag' or 'taringa.' It seems to be an accident that might well happen again, for, from the account of the men who, deceived by its similarity to the herb which they are accustomed to gather and eat with their food in their native hills of Nepal, partook of the plant in question and were poisoned, there is a very great resemblance between the two. On the night of May 20th, 1891, I was summoned by the hospital assistant of my regiment, then in camp at Seri on the Black Mountain, to the lines of No. 5 Company Ghoorkas, being told that seven or eight men were lying in various degrees of delirium and unconsciousness, which had come on shortly after they had eaten their evening meal. On reaching the tents I found a havildar and seven men, all Ghoorkas, suffering from a series of symptoms which were very distinctive of belladonna poisoning—viz., marked dilatation of the pupils, a feeling of constriction in and dryness of the throat, a peculiar variety of fussy delirium, with hallucinations, and the loss of power of coördination in the lower extremities. Ascertaining that all had eaten the leaves

and stalks of a plant they called *tambaku sag*, which had been given them by some men of their own company on picquet some 1500 feet higher up the hill, whom they had that afternoon been to visit, I examined at once a specimen of the plant lying near, and from a certain resemblance of the leaf to that of belladonna and that of the symptoms to those of belladonna poisoning I first thought it might be a variety of that plant, and after giving each man sixty grains of lime sulphate, which produced emesis in every case, I administered morphine hypodermically to the two worst cases, and had all taken to the nearest field hospital. Arrived there, the next three hours were employed in giving ammoniac carbonas to induce emesis and then in keeping the men constantly moving. This treatment answered very well, and by 2.30 A.M. all were in a condition which permitted of their being put into tents, a careful watch being maintained upon them. The havildar, who throughout seemed least affected, returned to the regiment next day and the remaining seven men the day following. I examined all in the day on which they returned to the regiment and found they were still suffering from various degrees of dilatation of the pupils, inability to accommodate, and giddiness. All these symptoms, however, entirely disappeared in a day or two, and the men were sent back to duty. Their symptoms from the beginning and more in detail were as follows. Some fifteen minutes after first eating the herb they said that they began to experience a feeling of constriction in and dryness of the throat, soon amounting to an inability to swallow, rapidly succeeded by a sense of muscular weakness and tremors so marked that they found themselves without sufficient strength to continue to break and eat their chapatties; giddiness and inability to stand upright were next experienced, and finally the condition of delirium and semi-consciousness supervened in which I found them. To this it may be added by way of fuller description that most of them were unable to answer when spoken to, and those who could had forgotten their own names. Some lay on the ground in a dazed condition others sat up constantly making fidgety movements with their fingers, picking up small particles of sand or pebbles from the ground, or appearing to be searching for something they had lost, and occasionally looking up with a half vacant, half wild expression. In none was there anything approaching a state of collapse; the pulse was good if a trifle rapid; in all respiration was never stertorous; no pain was complained of save the dryness of the throat and the painful sense of constriction. The mouth was dry and salivary secretion arrested. They exhibited all varieties of gait, from trifling unsteadiness to complete loss of control over their lower limbs. It being dark and all quiet in camp and the men being together, their condition for some time escaped notice, and it was not until nearly three hours had elapsed after eating the herb that I was called to them. It seemed fortunate, therefore, that their condition had not become more serious. Four had vomited before the emetic was given them; only one had passed urine before losing consciousness, and then in small quantity and with some amount of strangury. I very much regret that I am unable to show a specimen of the plant, which, however, was submitted for identification at the time, and presumed, without much doubt, by an experienced botanist to be *scopolia lurida*. The plant grew very locally at an elevation of from 7000 to 8000 feet, and occurred rarely. The plant for which it was mistaken is, the men say, very similar in appearance, and is known by them in Nepal as 'taringa' or 'tambaku sag.' There is said to be this important difference—viz., that the stalk of *tambaku sag* is hollow, while that of *scopolia lurida* is certainly solid and succulent; but, never having seen the plant, I am unable to speak with certainty on the point, and had I thought of it before I would have tried to procure a specimen for comparison, and much regret that the interest, if any, that the note has should be so greatly lessened by the want of specimens both of *tambaku sag* and *scopolia lurida*."

A Remarkable Case of Quinine Poisoning.

Surgeon-Captain A. ERNEST ROBERTS, M.B., Civil Surgeon, Aligarh, North-West Provinces, read a paper upon the following case of Quinine Poisoning, saying:—

"As far as I can ascertain, the subject of poisoning by quinine has not received much attention from medical authors—at any rate, I have not been fortunate in my researches into medical literature in obtaining light and leading upon this subject. I am therefore impelled to put the following case on record as one of remarkable interest in many ways. An Eurasian woman, aged thirty-five, married,

¹ Archives de Toxicologie et de Gynécologie, February, 1895.

no children, in comfortable circumstances, had always enjoyed good general health, but had been troubled for nearly two years with menorrhagia associated with slight uterine retroflexion. This local trouble had been temporarily overcome by treatment, and she had normal periods for three months, when at noon on a certain day in November, 1893, I was suddenly summoned to her bedside, as she was declared to be dying. On my arrival I heard that she had swallowed a very large dose of sulphate of quinine an hour or so before, and from the evidence available, which I carefully and critically weighed, I believe the quantity to have amounted to about six drachms. There is no doubt in my mind that she managed to swallow fully five drachms, and there were traces of a little in the vessel from which she drank it, and on her lips, at the time I first saw her. She was lying upon her bed totally unconscious—an inert paralysed mass. The whole surface of her body was deadly cold and blanched, or, rather, livid; her temperature (axilla) was 95° F., breathing almost imperceptible, shallow, and slow, and the pulse was 45 thin and small. Her eyes were closed, and the pupils were considerably dilated, there being no response to light; no tendon reflex was obtained and there was no response to external stimuli, and save that she at long intervals uttered a low groan she appeared to her friends to be dead. My own anticipations were not cheerful. There was little, if any, change in her condition for several hours, during which she vomited 'coffee-ground substance' several times. Indeed, definite and obvious signs of rallying were deferred until the early hours of the next day, and it was then ascertained that, in addition to slight deafness, she was 'stone blind,' even to total non-appreciation of strong sunlight. The deafness gave no trouble; perfect hearing was restored within a week, with the gradual return of general functional activity, but it was long ere all traces of the tremendous shock to the general system had disappeared, and doubtless the demoralisation induced by the blindness and the terrible circumstances served to accentuate the profound debility. I have said that at first the pupils were widely and equally dilated, and did not respond to the stimulus of light; the blindness was the dense, uncompromising darkness of atrophy. It was not until forty-eight hours had elapsed that I found an opportunity of using the ophthalmoscope, and the picture I obtained was definite and well marked. There was a blur or haze over the whole perceptible retinal field, there was a distinct deepening of colour (congestion), especially concentrated in the macula; the discs were not definitely altered in colour, but, if anything, perhaps also of a slightly deeper tint than normal (I speak under reserve, as I am not very familiar with the exact shade of the Eurasian disc), but hazy and with ill-defined margins. I can think of nothing more suggestive as an indication of the impressions I received during the first examinations than a rather highly coloured and crude water-colour sketch which had been very slightly smudged, perhaps I may call it 'smoky,' so that the contours of the vessels were blurred and not well defined. However, this stage was of short duration. The tint of congestion and the blur alike disappeared, and in a week from the onset I began to fear that optic atrophy would close the scene. The retinal vessels, both veins and arteries, became well defined and contracted, and the optic discs became distinctly pale; the pupils remained widely and equally dilated and insensible to light. I made frequent and regular examinations, but my powers of observation did not avail to detect any very decided change in the ophthalmoscopic appearances during a period of quite three months. The general retinal ischæmia and disc pallor did indeed quickly become decided, and remained thus with no perceptible change for about six weeks, when a very slight improvement set in. During the fourth and fifth month a certain distinct but small improvement could be noted at considerable intervals, but when I left my charge for six months' leave the retinal anæmia was still the notable objective sign, the disc having fairly regained its normal tint. So far for the objective signs. As regards the subjective I may briefly add the following particulars. The absolute 'stone blindness' lasted, I believe, for fully two weeks; the first perception after that was the flash of light from the ophthalmoscopic mirror, but there was no perception of external objects until the third or fourth week, when certain things—a small bright metal time-piece, the looming figure of an individual—were seen at a distance of four to eight yards. This distant vision was a marked feature of the case for two or three months, and though it gradually gained in distinctness of outline and

detail was a blurred impression on a dim and hazy background. A noticeable point during the fourth week also was her perception at a distance of dark linear objects—e.g., the parallel beams of the roof of the bungalow and the cross bars of the windows in the doorways. Here also the definite objective points were lost in an indefinable haze. It was somewhat surprising that she could occasionally read the dial of the clock before mentioned at four or five yards distance, but could distinguish no neighbouring object. Colour blindness was marked from the first, but about the sixth week she noted the dark blue of my necktie; red and yellow were, and are still, best distinguished. From the sixth to the eighth week onward, with occasional relapses synchronous with a return of the menorrhagia and other disturbances of the general health, she gained ground in all points, very slowly but surely, and in April last she could write a letter and read large type, the effort being exhausting to her visual faculty, and consequently not persevered in. At this stage I lost sight of the case owing to my departure on leave, but I have recently heard from my patient that, although much better in most respects, there is much left to be desired in her visual powers; she gets about, reads and writes, and uses her mirror satisfactorily for toilet purposes, but her colour vision is defective, red and yellow being still most easily distinguished, and these at a distance, nearness of approach causing objects to appear black, the general hazy blur of the background of the visual field being also a trouble to her."

[Surgeon-Captain Roberts does not say what treatment (if any other than expectant) he employed.—ED. L.]

DEC. 27TH.

Strychnine in Cases of Snake-bite.

Surgeon-Captain J. J. PRATT, I.M.S., civil surgeon, Gonda, read a paper upon Strychnine in cases of Snake-bite. In this paper he said:—

"During the past two years I have had the opportunity of applying the method of treatment recommended by Dr. Mueller in cases of snake-bite on two occasions. The first case occurred at Fyzabad and was treated by Surgeon-Major Cadge, I.M.S., and myself. The particulars are as follows: A Hindu male aged twelve years was admitted into the Fyzabad Sadr Dispensary about 7 A.M. on the morning of July 26th, 1892. Patient was accompanied by his father, who stated that half an hour previously, when the boy was seated at his morning meal, a snake suddenly appeared and bit him on the great toe of the left foot. He (the father) at once enveloped his hand in a cloth, seized the snake close to its head, tore it from the boy's foot, and hurled it some distance, where it was promptly killed by a police constable. This statement was confirmed by other spectators. The snake, which was brought to the dispensary with the boy, was a cobra 3 ft. 3 in. in length and of dark-grey colour. The boy on admission complained of pain, tingling, and numbness in the left foot. The surface of his body was cold and he appeared to be a little drowsy, but there were no marked general symptoms. On examination of the foot a distinct puncture was found on the upper and inner surface of the great toe about an eighth of an inch from the edge of the nail. There was slight bleeding from the puncture and the skin immediately around it was ecchymosed. The toe was distinctly swollen. No second puncture could be discovered, this being probably due to the horny nature of the thickened epithelium of the part. A crucial incision was at once made at the site of the puncture, the wound washed with a strong solution of permanganate of potassium, and a bandage tightly applied round the leg above the ankle. Five minims of the ordinary pharmacopœial solution of strychnine were then injected hypodermically, and the injection repeated every five minutes. After the seventh injection the patient was seized with tetanic spasms and vomited. Treatment was then suspended for the space of an hour and a half, when drowsiness became very marked. The injections were accordingly resumed at intervals of ten minutes, and after the sixth dose (being the thirteenth in all), when a total of sixty-five minims had been injected, a severe spasmodic fit came on. This was at 11.10 A.M. Between 11.15 and 11.45 A.M. a succession of severe tetanic spasms occurred, the muscles of the abdomen, back, and thighs being chiefly affected. The pulse became feeble and fluttering—140 to the minute—and respiration almost ceased. For a short time it almost appeared as if the patient were about to succumb to the effects of the 'remedy.' Small quantities

of brandy and extract of chicken were administered and swallowed with difficulty. The temperature was found to be slightly above the normal. Between noon and 1 P.M. patient's condition improved, the spasms being few and slight. In the course of the following hour they ceased entirely. The temperature at 3 P.M. was 103° F. The patient was perfectly conscious and complained only of the tightness of the ligature on his leg; the foot was much swollen. Nourishment was taken in small quantities. At 6.30 P.M. the ligature was removed without causing any untoward symptoms. At 6 A.M. on the 27th the temperature was 101° and fell to normal in the course of the day; the pulse was good; there was no pain. The swelling of the foot rapidly subsided; no further symptoms appeared and the boy left the dispensary on the morning of July 29th in perfect health, with the exception of a trivial wound on his toe. The second case occurred in my own compound at Gonda, and was treated by my assistant surgeon and myself. A Hindu female aged twenty-five, the wife of one of my servants, was bitten by a snake about 2 A.M. on June 15th, 1894, whilst lying asleep on the floor of her house. The snake, described by the woman's husband as 'kala,' escaped. Assistance was not applied for until 3.30 A.M. (an hour and a half after the infliction of the bite), by which time the patient had developed marked general symptoms, notably drowsiness and loss of power in the legs, being unable to walk or stand by herself. Great pain was complained of at the seat of the bite, which was found to be the inner side of the left arm close to the posterior axillary fold. Two distinct punctures were visible about three-quarters of an inch apart. The surface of the skin was cold and clammy, the pulse feeble, and respiration slow and sobbing. At 3.45 A.M. one-fifteenth of a grain of strychnia was injected hypodermically, and the patient sent on to the Sadr Dispensary for treatment to be continued. At 4 A.M. the patient arrived at the dispensary insensible, with profuse salivation, hands and feet cold, conjunctivæ congested, pupils normal, and pulse feeble. Fifteen minims of the B.P. solution of strychnia were at once injected. At 4.15 A.M. there was no improvement; the pulse was feebler and slower, breathing stertorous, and the face was becoming cyanosed. The injection was repeated. At 4.30 A.M. the face and hands were markedly cyanotic, the pulse being feeble and at times intermittent, the surface of the body cold, and the respiration 6 to the minute. The injection was repeated. At 4.45 A.M. the patient died. Three days later a large cobra was killed in the hut in which the woman had been bitten. The first of these cases is complete as far as it goes. The snake was produced with the patient; strychnia was administered in what under ordinary circumstances would be regarded as dangerous, perhaps deadly doses; the symptoms produced by the drug were for a short time alarming but soon passed off, and the boy made a rapid recovery. The only element of doubt attaching to the case is whether the bite inflicted by the snake was really an effective one. Only one puncture was discovered, and the quantity of venom injected may have been small, or one may go even further and suggest the possibility of the cobra having bitten the boy without injecting any poison at all. It is possible that many authentic recoveries, supposed to be due to the administration of antidotes, are really due to the bites not having been vicious. The second case was unsatisfactory from the commencement. The period which had elapsed before medical aid was sought and the position of the bite in close proximity to the trunk were unfavourable to the successful adoption of any line of treatment. No ligature could be applied above the bite, and the patient's condition showed it to be certain that local treatment would be of no avail. Within the short period of an hour more than half a grain of strychnia was administered without the slightest sign of even temporary improvement. Perhaps the doses should have been larger. My mind remains open on the question of the efficacy or inefficacy of Mueller's method of treatment. I always look forward with interest to accounts of cases in which it has been adopted by other medical men, and shall not hesitate to give it a further trial myself should the opportunity offer. In view, however, of the many doubtful cases which have been published, I wish to close my paper with a humble expression of opinion to the effect that the great majority of cases of so-called 'cure' of snake-bite, in which the offending reptile has neither been killed nor captured and subsequently identified by a competent authority, are of absolutely no scientific value."

SURGERY AND OPHTHALMOLOGY.

DEC. 27TH, 1894.

The following are abstracts of papers read in the Section of Surgery and Ophthalmology:—

Conjunctivitis in Gaols.

A. RAGASINGHAM, M.B., C.M., Assistant Medical Officer, Convict Hospital, Colombo, read a paper upon Conjunctivitis in Gaols. In this paper he said:—

"The following notes were compiled from the cases of conjunctivitis treated at the Convict Hospital, Colombo, from Jan. 1st, 1894, to Nov. 7th of the same year. This gaol is the largest in the island, and the cases treated here may be taken as a fair type of the disease as met with in the Ceylon prisons. Some of the cases treated here were extremely mild, while others were of the most severe type, and a very large number may be assigned to the class of considerable severity. Almost all the cases treated in this gaol were in males, and the females, though few in number comparatively, were almost exempt from this disease; and hence it would be reasonable to conclude that male prisoners, from hard work, exposure to the sun, and the intrinsic nature of their occupations, are more liable to this disease than females. It would hardly be necessary to premise here that among the gaol population all diseases, especially conjunctivitis, would be brought under treatment from the very onset; and hence the relative value of the following figures, and the conclusions drawn from them must be placed on a somewhat different footing from the statistics of the civil hospitals and private practice. By careful calculation the average stay in hospital of an individual is found to be 5.37 days, the maximum being 76 days and the minimum 1 day. But when a patient had stayed in hospital more than 16 days, some other complication or intercurrent disease must be searched for. It is almost self-evident that certain trades and occupations, such as masonry, lime-making, stone-cutting, stone-polishing, sledging, brick-making, would predispose labourers to conjunctivitis, and these presumptions are fully borne out by figures. The annexed table would make this plain:—

Occupation in Gaol.	No. of cases.
Mason's party	374
Husk-beating	128
Sand party	32
Levelling party	18
Latrine party	15
Fencing party	14
Cleaners and sweepers' party	10
Cabbok-cutting party	7
Stone-cutting and breaking party	6
Hospital attendants	3
Lamp lighter	1
Other parties	—

"I should not omit to mention here that trachoma forms an important factor both in causing this disease and in bringing on unfavourable results, and it is in such cases that general ulceration and sloughing of the cornea are liable to supervene owing to the nutrient material failing to reach the corneal cells. If trachoma and oedema of the lids should exist simultaneously the unfavourable termination would be brought on much earlier. The various seasons of the year exert a powerful influence both in predisposing to and exciting this disease. Thus April shows the largest number and October the smallest according to the statistics of the hospital. The following table illustrates this point.

Number of Cases treated in the Various Months.

January	40	August	64
February	101	September	53
March	110	October	51
April	121	November	16
May	57		
June	70	Total	745
July	62		

In a gaol where the number of inmates is limited, it is not an uncommon thing for one person to be readmitted again and again, at short intervals, for the same disease, and conjunctivitis is no exception to this rule; and the annexed table and chart show how many times certain number of men were admitted for this disease. I should not omit to mention in this connexion that in gaols a certain number of cases of conjunctivitis are self-induced, and are to be attributed to malpractices, such as the application of the juice of the croton seeds, lime, seeds of the castor-oil plant, emplastrum cantharidis, when applied externally for the legitimate purpose of causing a blister. Except in the early stages such cases cannot be diagnosed from the genuine conjunctivitis. I have also noticed that in tropical climates, such as those of Ceylon and India, hypertrophy of the follicles of the eyelids are much more common than in temperate climates like

Scotland and England; and I cannot but attribute this disorder mainly to any other influence but heat and direct exposure to the burning rays of a tropical sun. When applied to the head ice relieves the feeling of oppression and weight in the head, and tends to reduce the oedema of the lids. It relieves insomnia in certain cases of acute conjunctivitis. As a rule, preparations of opium are freely used internally, but chloral and bromide are used if insomnia is troublesome. I have noticed that a favourable position would tend to reduce the excessive oedema of the lids, especially in old, weak, and debilitated subjects. Thus, if a patient should sleep on the unaffected side the swelling would tend to decrease, and *vice versa*. It is routine practice to administer a drastic purgative like magnesium sulphate at the commencement of all cases of conjunctivitis provided that there are no contra-indications, and I have some faith in this preliminary procedure. Of the 750 cases treated all invariably recovered except one, an old emaciated individual about sixty-five years of age suffering from trachoma. In this case swelling of the lids was excessive, and in two or three days sloughing of the conjunctiva set in, and the patient lost the sight in this eye almost completely. Here strong solutions of nitrate of silver proved of no avail, and every other mode of treatment failed. The age of the patient and the condition of the lids would explain the cause of failure."

Some Difficult Cases of Chloroform Administration.

Mr. ARTHUR NEVE, F.R.C.S. Edin., in a paper upon Some Difficult Cases of Chloroform Administration, said:

"The fact that for all practical purposes ether is not available as an anæsthetic in India should enable the profession here to regard the chloroform controversy from an unbiased standpoint. Here it is not a matter of choice; but it is not reasonable to declare that because chloroform is the only available general anæsthetic in India, therefore it is the best in a cool climate. Nor, if it could be proved that it is absolutely safe in this country, should we settle the controversy in that way. India could contribute two important facts, which perhaps may be elucidated at this great gathering. First, the relation of race to anæsthetics, and this might include the question of racial habits, such as vegetarian diet and abstinence from alcohol. Secondly, the effect of temperature and altitude upon chloroform anæsthesia. Can any clinical difference be established between the administration to natives of India of chloroform in hot weather with a mean temperature of over 85° F., or in cold weather with a mean temperature of 50° or lower at such stations as these temperatures exist, and does an altitude of 6000 or 8000 feet affect the question clinically? These practical contributions to debatable points might reasonably be speedily expected from Indian surgeons. A New Zealand surgeon claims that careful study of cases shows that the aborigines there are less liable to suffer from shock, and that Europeans, if insufficiently anæsthetised, are apt to die from inhibition of the action of the heart. Does Indian experience homologate this view? Could an Indian committee be formed to investigate all fatal cases occurring in this country? I published a case in THE LANCET¹ in which partial anæsthesia *plus* shock caused very serious symptoms. It referred to a strong Kashmiri who required castration for sarcoma of a testicle. Owing to vomiting the anæsthetic was insufficiently administered; and at the moment of applying a clamp to the cord the patient became rigid, as in a tetanic spasm, and the heart's action stopped; the wound ceased to bleed. With difficulty—after inversion, injection of ammonia, and also per rectum of hot water, together with steady artificial respiration—the pulse began to flicker, the chest heaved, and the patient was restored. As he was sensitive to the knife I then rapidly administered two drachms of chloroform, which the patient inhaled quietly, and the operation was finished deliberately and safely. I am convinced of the importance of this and similar cases. One which I narrated at the meeting of the British Medical Association at Bournemouth has the same lesson. A patient suffered both from severe heart disease and from stone in the bladder. Chloroform was timidly given, and as the staff was inserted the patient gave a gasp and fainted. He was with difficulty restored to consciousness. A fortnight later I arrived in the town and was consulted. I offered to administer chloroform myself. Two drachms were given and the operation was begun. As the patient had taken chloroform quietly all seemed well, and I was asked to assist in the operation, leaving the house surgeon to continue the administration. Scarcely two minutes had passed before the breathing

appeared to stop. What was the cause? An overdose? No, for no more chloroform had been added. It was the shock acting reflexly on a heart neither protected by consciousness nor by full anæsthesia. I append two cases of faulty administration that have occurred this year out of over 500 chloroformisations under my care. In both cases I was summoned from an adjoining room where I was operating. In one a native assistant of considerable experience was operating while another, who has chloroformed thousands of patients, gave the anæsthetic. When I entered the patient had been partially inverted, the operator was performing artificial respiration, while the other drew on the tongue with the head back; but observing that the lips were purple, which was evidence of continued action of the heart, I at once put my finger down behind the tongue and raised the epiglottis. Immediately one heard the air rush into the chest, and in less than a minute a sighing inspiration showed that natural respiration was recommencing. In this case I think an overdose had been given and the tongue had fallen back, and the traction upon it did not suffice to open a flaccid epiglottis. The other case was one in which chloroform had been badly taken, the patient struggling a little and afterwards incessantly spitting. Anæsthesia was pushed to stop this annoying reflex symptom and the moment it ceased the respiration also stopped and the patient turned pallid. When called in I lifted him on to the ground with his feet and body up and began artificial respiration; the air entered the chest, but for a few seconds the absolute pallor remained. Then there was a slow, natural inspiration; recovery was slow for a minute, and then, with a heave of the body, vomiting began, and the stomach emptied itself of two pounds of semi-digested rice. Here, as in other cases, the syncope was connected with a full stomach and was premonitory of the vomiting. There were two other cases very noteworthy. One was a woman with a gumma over the thyroid cartilage, with considerable dyspnoea, and a constant spasmodic cough. I administered chloroform myself, and began with a dose of ten minims on a towel. There was a moment of struggle, then she lay senseless, and the operation was begun. Her breathing was almost imperceptible and the pulse thready. No more chloroform was given, and the operation (which lasted about twenty minutes) was completed without a sign of consciousness, but soon afterwards she came slowly round. The other case was that of a lad with very great dyspnoea from the pressure of a goitre which with each inspiration was sucked down behind the sternum. As in the earlier case only a few drops of chloroform were given, Mr. W. F. Adams kindly taking charge of its administration. I had well begun the operation when breathing stopped, and also the bleeding except some venous oozing. No more chloroform was given. The legs were raised and artificial respiration began &c. I went on with the operation and removed the portions of the goitre resting over the trachea. Still he remained unconscious, with great dyspnoea, owing to the flattened and infantile condition of the trachea, so I proceeded to open the trachea below the cricoid cartilage. An ordinary tracheotomy tube gave no relief, so I inserted a gum elastic catheter for three inches down the trachea. Shortly after this the patient began to show symptoms of returning consciousness. In both these cases the blood was very venous, and the poisonous effect of the chloroform upon the medulla oblongata was at once manifested even in minute doses. There have been upwards of six thousand administrations of chloroform since 1875, without a single direct or indirect death, in the Kashmir Mission Hospital, though not a year passes without dangerous symptoms occurring in a few cases. We have seen (1) primary syncope from fear, and also from (2) laryngeal spasm; (3) secondary syncope from shock due to insufficient chloroform, and also from a proper dose acting on non-oxygenated nerve centres; (4) tertiary (sometimes secondary) syncope connected with vomiting; (5) apnoea from (a) mechanical causes, (b) spasm of the larynx, and (c) from the toxic action of an overdose (relative or absolute) on the nervous centres. In any of these ways life may be lost. The surgeon must hold clear views on the method of administration, so as to steer as clear as may be practicable in any given case of these various dangers; and he must be prompt to recognise the danger signals of a dilated pupil, or gasping or stertorous breathing, or change of colour in the lips. He must also be thorough as well as prompt in his method of restoration. If he have fewer accidents than his fellows let him not attribute any special credit to himself, still less apportion blame to his neighbours, for the time may be near when he will himself meet with a fatal case due to idiosyncrasy of the patient."

¹ THE LANCET, Dec. 17th, 1892.

Obituary.

SIR WILLIAM SCOVELL SAVORY, BART., F.R.S.,
LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND;
CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

"THE angel of death has passed over this land; you can almost hear the beating of his wings." These words of one of England's greatest orators must be in many men's minds to-day, and to our profession they must appeal with special force, since in the short space of fifteen days two of the foremost in the realm of surgery have ended their labours. Scarcely had John Whitaker Hulke been laid to his rest than he is followed by his intimate friend and fellow worker, William Scovell Savory.

William Scovell Savory was born in 1826 on Nov. 30th (St. Andrew's Day). He was educated at a private school at Ramsgate, under Mr. Darnall, whose name is inseparably connected with copy-books. Whilst at school he already showed signs of the declamatory and oratorical powers which were so noticeable in his after career, it being on record that on one occasion he took the part of Cato in Addison's tragedy with great success. Several years afterwards he could repeat many of the lines, and was specially fond of quoting those two lines so appropriate, as future events showed, to himself:

"Tis not in mortals to command
success,
But we'll do more, Sempronius,
we'll deserve it!"

He entered as a student at St. Bartholomew's Hospital immediately after leaving school, and was a most regular attendant at lectures, so much so that once when later in his life he was speaking to some students about irregular attendance, he said that he never remembered missing one of the lectures of Sir James Paget, which began with the utmost punctuality every morning at nine; nor was he ever late, though living at that time at Oakley-crescent, in the City-road. His work in the out-patient room and in the other practical departments of his hospital education was not less systematic. He dressed for Sir William Lawrence and clerked for Sir George Burrows, both of whom entertained a very high opinion of his abilities. At a very early period Mr. Skey formed a strong attachment to him, and took him to most of his operations; while in his "Treatise on Surgery" the same surgeon paid a tribute to his pupil's knowledge and predicted his future success. Mr. Savory read and materially modified the proof-sheets of this work, and wrote the whole of the chapter devoted to the diseases of the eye, which is sufficient testimony to the position of esteem which he occupied in his senior's mind. From student days he was a born orator and debater. At the Abernethian Society of St. Bartholomew's Hospital he always argued well. If in the chair he could always sum up better than any other member, while in discussion he could take either side with equal ease, often opposing for the mere love of argument. His scholastic career was brief and creditable, as would be expected from a student possessed in so marked a manner of the virtues of industry and punctuality and the talent of a lucidity amounting almost to genius. In 1847 he was admitted a Member of the Royal College of Surgeons of England, and in 1848 he graduated as Bachelor of Medicine at the University of London, where he was University Medical Scholar. In 1852 he was admitted a Fellow of the Royal College of Surgeons, from which date he

devoted himself entirely to surgical teaching and practice. His first teaching appointment was that of Demonstrator of Anatomy at St. Bartholomew's Hospital, and this was followed by his succeeding Sir James Paget in 1859 as Demonstrator and Lecturer in Physiology. He was elected assistant surgeon to the hospital on April 24th, 1861, and full surgeon on the same day in 1867. This latter position he held until Nov. 12th, 1891, when he resigned, and was at once elected consulting surgeon, which office he held until his death. In May, 1869, he was appointed Joint Lecturer on Surgery with Mr. Coote, and ten years later, on the death of Mr. Callender, was made sole lecturer, which position he retained until 1889, when he resigned his post.

As a lecturer Sir William Savory was a worthy successor of Lawrence, Paget, and West, resembling in manner and delivery Lawrence the most. His lectures were absolute models. Clear, lucid, every sentence weighed and polished, with diction perfectly distinct, the mobile, sensitive face would brighten with a singularly charming smile as he referred to his great predecessors in the field of surgery; all this made his lectures appear something very different to the ordinary routine of the work of a medical school, and so they were felt to be by all his pupils. Not only did the students of the hospital—sometimes, it must be said, slow to recognise an intellectual treat—attend and listen, but many a man from the staff of

other hospitals came and profited by the great teacher's clear logic and intense sympathy with his subject. In his visits to the wards he was sparing of speech and the value of his clinical teaching was more in what he did than in what he said. Those who took the pains to watch his practice could always draw from it clear rules and close reasonings. But he was not a popular bedside teacher. His extreme modesty, so graceful in one possessing such splendid endowments, repressed the outpouring of his abundant thoughts and gave to his public manner a certain degree of severity. In the student he oftentimes inspired something akin to awe, which was due to his impressive demeanour and eagle glance (it is a hackneyed phrase, but the only one that really expresses the quality of his acute gaze), a glance which inspired an uneasy consciousness that ignorance under its influence

SIR WILLIAM SCOVELL SAVORY, BART., F.R.S.

was certain to betray itself. But he was always ready to impart information and would take much trouble to discuss any subject of interest propounded by an intelligent questioner, pouring forth for his benefit a flood of light and knowledge. Perhaps he was seen at his best in the operating theatre on consultation days, when, in the discussion of an obscure or doubtful case, no one could excel him in the manner in which he would state the possible causes of the symptoms observed or in explaining the reasons which made him take up the particular view he held. Without being a brilliant operator he had the advantage of being ambidextrous, a faculty that on occasion served him well. Like that of his master, Lawrence, his surgery was eminently sound, and his results compared favourably with those of others both before and after the introduction of rigid asepsis. If he was slow to adopt innovations, it was the effect of a righteous desire not to endanger the patient's chances by anything in the nature of an experiment. As an operator he trod the highways of surgery. He was very sure in all that he did, and the patient ran no risk of injury in addition to that pertaining to the operation. With a nervous system highly strung it was no wonder that at times during an operation he should show signs of the strain, but he never lost his self-possession, and in moments of the greatest excitement, even of dire emergency, his intellect maintained its sway and directed his hand aright.

The position that he gained in the medical profession would have been his, we believe, in that of the law. His clear and subtle as well as logical mind would have found a congenial field in summing up an intricate chain of evidence. He would have shone on the bench. He had a singular faculty of unfolding an argument in a calm judicial manner, his ideas flowing in due sequence, the language being always equal to the occasion, and the opinions delivered with a voice of skilled modulation and without the slightest hesitation. His opinion consequently carried great weight with it. He was ready, too, in debate, carrying out his early promise to which we have referred. No one could be more prompt to detect a flaw in an opponent's argument or quick to expose it with pitiless sarcasm and ridicule; yet he was not easily put out of temper, and bore buffeting with a smile. This dialectic facility showed itself to great advantage in the somewhat heated debates which took place at the Royal College of Surgeons of England during his Presidency with reference to reforms in the government and constitution of that body. For though many a time he stood almost alone as regarded his views in the presence of a large body of opponents, he seldom failed to make his point or to keep matters in the paths which, rightly or wrongly, he regarded as the safest and best for the interests of the College.

In every branch of learning he was capable of making the best of what he knew. On one occasion he had just laboriously, with dictionary in hand, gone through the book of the "Odyssey," then required by the regulations for the preliminary examination for the Fellowship, and in a circle of some half-dozen men, the late Professor Rolleston, a most accomplished Greek scholar, made a casual remark to the effect that there was no example of a word with a certain number of feet at the close of a line in Homer. Savory objected, and, to Rolleston's intense astonishment, quoted the line he had only the previous evening read, in refutation of the really learned classic's view. He had a great faculty for criticism, and enjoyed nothing more than to discuss and comment upon the characters and situations in the books he read. He was not a voluminous writer, but his essays on Pyæmia, which appeared in the St. Bartholomew's Hospital Reports, and his scholarly "Lectures on Life and Death," delivered at the Royal Institution, are classics. He was very reserved, and modest to a fault, a thorough and sincere Christian, though he never paraded his religion.

These are the main facts in Sir William Savory's career, and the salient qualities of his character. They tell a simple, straightforward story of honesty, industry, and high intellectual endowment meeting with their due rewards, and as such require no commentary from our pen. The unique esteem in which he was held by the surgeons of his time is testified by the fact that he was President of the Royal College of Surgeons of England for five years in succession, an absolutely unprecedented occurrence; while the royal favour of a baronetcy was not without special features in his case, as it is an open secret that he had refused lesser honours. So passes a great man, not only from his professional ability, but from his hatred of shams and self-advertisement—one who, like his great master, John Hunter, was, to use his own words, "tempted by no seductive theory into undue haste, was hardly ever lost in an unsound conclusion. A man of indefatigable industry, of unquenchable energy, of singleness of purpose, and unbounded sacrifice."¹

A few details of his last illness will be read with melancholy interest. On Thursday, Feb. 21st, he complained of not feeling well and consulted Dr. Habershon, who took him on the next day to see Dr. Pavy. Some slight improvement was manifest until the 28th, on which day he visited St. Bartholomew's Hospital. There were several cases of influenza in the house, and on the morning of March 1st his temperature, which was subnormal on the previous day, was found to be elevated, though beyond a slight bronchial catarrh none of the specific symptoms of influenza were present. Sir William Savory was, however, kept to his room, and on the following day symptoms of bronchitis supervened, though at no time severe, and his strength was well maintained until the afternoon of Sunday, the 3rd inst., when for the first time signs of prostration and cardiac failure appeared. At night there was a decided rally, with improved pulse and lower temperature. During the early hours of Monday morning, the 4th inst., the temperature again rose, sudden and profound collapse set in, and in spite of all that the most active

stimulation and the most assiduous care could do, he sank at 10.30 A.M. During his illness he was under the care of Dr. Pavy and Dr. Habershon, and was nursed by his daughter-in-law and Sister John from St. Bartholomew's Hospital.

Sir William Savory married in 1854, on his birthday, the daughter of William Borradaile. She died in 1863. By her he had one son, who succeeds him in the title and is incumbent of St. Bartholomew the Great, Smithfield.

A memorial service was held on Thursday in St. George's, Hanover-square, at 1.30 P.M., and the interment took place in Highgate Cemetery on the same day.

SAMUEL HOPPER ADAMS, M.D. LOND., M.R.C.S.

DR. ADAMS, who died on the 1st inst. after a final illness of a few hours' duration, was educated at the Bedford Modern School, whence he proceeded to University College Hospital. He matriculated at the same time at the University of London, obtaining high honours in Botany, a love of which science he retained throughout life. Professor Hillhouse of Birmingham and Professor Green of the Pharmaceutical Society owe, we believe, their first botanical training to Dr. Adams. He had a distinguished career at the University of London, where he took his M.B. in 1859 as a medalist, and proceeded to the M.D. degree in 1861, having become M.R.C.S. in 1858. At an early period of his professional life he served as a surgeon in the Peninsular and Oriental Company. During this time he had an attack of sunstroke in the Red Sea, to which may be traced the weak state of his health in after years. He settled in Bedford, where for several years he was in partnership, but afterwards practised independently. He was greatly esteemed by his patients and by his medical brethren. His unobtrusive and kindly manner, together with his knowledge of many scientific subjects, procured him many friends. His position as surgeon to the Bedford Provident Dispensary brought him in contact with a large number of the humbler classes, to whom he greatly endeared himself, and who showed their appreciation of his faithful services by following his remains to the grave. He was buried according to the rites of the Moravian Church, of which he was a member and a churchwarden. He leaves a widow and three children.

SAMUEL CHARLESWORTH HIRST, M.D. ST. AND., M.R.C.S. ENG., L.S.A. LOND., J.P.

GENERAL regret has been caused among a large circle in Bradford by the announcement of the death of Dr. Hirst, late of Planetrees House, Laisterdyke, Bradford, who passed away at Southport on Feb. 27th. It is only about eighteen months since he left Bradford, where he had practised for more than twenty years and had made many friends by his benevolence and zeal for good works. Having studied at the Leeds School of Medicine he qualified as M.R.C.S. in 1861 and as L.S.A. in 1867. In 1887 he graduated as M.D. at St. Andrews University. He was a consistent but not an aggressive politician, and was one of the Bradford borough magistrates.

MARSHALL HALL HIGGINBOTTOM, M.R.C.S. ENG., L.S.A. LOND.

THE death is announced of Mr. Higginbottom of Nottingham, who succumbed on Feb. 24th to an attack of pneumonia. The deceased gentleman, who was born in 1822, was a son of Mr. John Higginbottom, F.R.S., of Nottingham, and a nephew of the celebrated Dr. Marshall Hall of London. He was a student at Guy's and St. Thomas's Hospitals, and after having obtained the diploma of the Royal College of Surgeons of England in 1844, and that of the Apothecaries' Society in 1845, he travelled to Constantinople and other parts of Eastern Europe. Returning to England he went into partnership with his father, and lived to be one of the oldest members of the medical profession in Nottingham.

Medical News.

UNIVERSITY OF LONDON.—The following candidates passed the Intermediate Examination in Medicine in January, 1895:—

ENTIRE EXAMINATION.

SECOND DIVISION.

Arthur, Joseph Hugh, London Hospital.
 Bell, William Blair, King's College.
 Bennett, Harry Charles Plant, St. Bartholomew's Hospital.
 Bergin, William Maraduke, University College, Bristol, and Clifton Laboratory.
 Brown, Robert Pollock, St. Bartholomew's Hospital.
 Chennells, Ernest Philip, University College.
 Christian, John Beresford, St. George's Hospital.
 Clegg, William Wheelwright, Leeds, and Middlesex Hospital.
 Clifford, Frank Charles Weeks, King's College.
 Cobbletick, Arthur Stanley, Bristol Medical School.
 Evans, Evan, Guy's Hospital.
 Fitz-Hugh, Richard Truman, Guy's Hospital.
 Harris, Lucy Elizabeth, London School of Medicine and Birkbeck Institute.
 Hasselacher, Francis Joseph, King's College.
 Hodgson, Curtis Rawsthorne, Guy's Hospital.
 Knowles, Beatrice, London School of Medicine and Birkbeck Institute.
 Lewin, Octavia Margaret S., London School of Medicine for Women.
 Lucas, Joseph John Scammell, B.A., Bristol Medical School.
 Lynch, Stephen Frederick, King's College.
 Maxwell, Richard, London Hospital.
 Mayston, Robert William, Guy's Hospital.
 Michol, Frederic Archibald Hope, St. Mary's Hospital.
 Moore, Julius, Guy's Hospital.
 Mortimer, William Gradson, London Hospital.
 Payne, Alfred Ernest, St. Mary's Hospital.
 Phipps, John Hare, Owens College.
 Pritchard, Frank, Owens College.
 Starling, Hubert John, Guy's Hospital.
 Varley, William Crowther, Owens College.
 Walker, William Percival, Owens College.
 Walter, Albert Elijah, Middlesex Hospital.
 Webb, Bertha Margaret, London School of Medicine for Women.
 Wernet, August Joseph, Guy's Hospital.
 Wilshaw, Robert Heywood, Owens College.
 Woolcock, Harold Brookfield, Owens College.

EXCLUDING PHYSIOLOGY.

SECOND DIVISION.

Baker, Alfred Eaton, Middlesex Hospital.
 Bletchly, George Playne, Middlesex Hospital.
 Durrant, Charles Edwin, St. Thomas's Hospital.
 East, William Norwood, Guy's Hospital.
 Gunther, Hermann Arthur, University College.
 Hall, Edmond Stokes, Guy's Hospital.
 Hunt, Edward Lewis, St. George's Hospital.
 Marriage, Herbert James, St. Thomas's Hospital.
 Maxwell, James Laidlaw, St. Bartholomew's Hospital.
 Moore, Percy, Guy's Hospital.
 Northcote, Percy, St. Thomas's Hospital.
 Smith, Daniel Lloyd, Guy's Hospital.
 Thornton, Jeremiah, London Hospital and Birkbeck Institute.

PHYSIOLOGY ONLY.

FIRST DIVISION.

Scatchard, James Percival, St. Thomas's Hospital.
 Smith, Stanley Francis, St. Bartholomew's Hospital.

SECOND DIVISION.

Emms, Harry Robert, University College.
 Goode, Henry Norman, St. Thomas's Hospital.
 Greenwood, Frank Redmayne, Mason College.
 Harcourt, John Charles, St. Thomas's Hospital.
 Mantell, Hugh Fraser, St. Mary's Hospital.
 Mundy, Herbert, St. Bartholomew's Hospital.
 Read, Charles Stanford, University College.
 Riviere, Clive, St. Bartholomew's Hospital.
 Seal, Francis Montgomery, University College.
 Shepherd, Ernest, St. Mary's Hospital.
 Sibley, Reginald Oliver, St. Mary's Hospital.
 Sugden, Henry, St. Mary's Hospital.
 Trimble, Charles Edward, University College, London, Edinburgh University, and Extramural School.
 Whrangham, William, St. Bartholomew's Hospital.

LITERARY INTELLIGENCE.—The following works are announced by Messrs. J. & A. Churchill as nearly ready for publication:—"Mental Physiology, especially in its relation to Mental Disorders," with Illustrations, by Dr. T. B. Hislop, Assistant Physician, Bethlem Royal Hospital; "Elements of Health, an Introduction to the Study of Hygiene," with twenty-seven Illustrations, by Dr. Louis C. Parkes, Medical Officer of Health for Chelsea; and a "Manual of Botany," based on that of the late Professor Bentley, containing many new illustrations: Vol. I. "Morphology and Anatomy," by J. Reynolds Green, Sc.D., M.A., F.L.S., Professor of Botany to the Pharmaceutical Society of Great Britain and Examiner in Botany to the Universities of London and Glasgow.

HUNTERIAN SOCIETY.—At the first general meeting of the session for 1895-96, held at the London Institution on Feb. 27th, Mr. Charters J. Symonds, President, being in the chair, Professor Clifford Allbutt, Regius Professor of Medicine in the University of Cambridge, delivered the Hunterian Society Lecture. Professor Allbutt chose as his subject Senile Plethora or High Arterial Pressure in Elderly Persons. He first narrated several cases typical of the condition. They all presented the same features, "symptoms obscure in so far as any particular parts or organs were concerned, but obvious and miserable enough otherwise"; the patients were sluggish, sleepless, wretched on awaking of a morning, nervously perturbed, with "some of the classical symptoms of hysteria." In all there was a remarkably hard pulse with "thudding" aortic valve sound, and none of them showed any feature in the urine leading to any suspicion of incipient or established renal disease. All of them were relieved by drugs adapted to lower blood pressure, and relieved most strikingly. Occasional mercurial and saline purges and a course of iodide of potassium, pushed freely, the lecturer had found to give almost complete relief; nitro-glycerine was also useful. Professor Allbutt then proceeded to discuss the meaning and pathology of the condition. He had found it commoner in women than in men; gout, either declared or suspected, was much oftener absent than present, and renal disease and arterial degeneration were conspicuous by their absence also; and even "renal inadequacy" could be excluded; that the blood in senile plethora is at fault, primarily or secondarily, is probable; and that it is altered in some way which sets up peripheral arteriolar contraction was the conclusion, but "beyond this I feel unable to proceed, if, indeed, I ought to go so far." Notwithstanding his declared inability to elucidate completely the pathology of the condition, Professor Allbutt concluded his lecture with some most thoughtful and thought-arresting considerations of its possible etiological factors of such intense interest to his audience that a unanimous wish was expressed to see them published in full. After a hearty and sincere vote of thanks to the lecturer the meeting adjourned.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—The sixty-seventh annual court of the governors was held on Feb. 27th, under the presidency of Sir Julian Goldsmid, Bart., M.P., one of the Vice-Presidents of the hospital. There was a good attendance of governors, amongst whom were the following: Sir Gainsford Bruce, General Gordon Pritchard, C.B., Mr. Edward Masterman, Colonel Montefiore, Mrs. Garrett Anderson, M.D., Mr. A. Boyce Barrow, Mrs. Stanley Boyd, Mr. Holroyd Chaplin, Mr. Robert Hampson, Dr. T. Crawford Hayes, Mr. J. Miley, Mr. J. Grosvenor Mackinlay, Mr. F. G. Pridaux, Mr. G. F. Sheppard, J.P., and Mr. Henry Silver. Owing to the prevalence of influenza many governors were prevented from attending, among others being Sir Charles Hall, Q.C., M.P., Right Hon. James Spensfeld, Sir Henry Oakley, Dr. Alex. E. Marsden, and Mr. H. N. Custance. The report for the past year was read by Mr. C. W. Thies, the secretary. Sir Julian Goldsmid, in moving the adoption of the report, stated that the new front building completed the work of reconstruction commenced forty years since, and provided greatly improved accommodation for casualty patients, dispensary, resident medical officers and servants, also much needed isolation wards; and that many other important and necessary improvements had been carried out in various parts of the hospital. The total cost of the works had been about £30,000, towards which the sum of £24,000 had been raised, leaving a deficit of about £6000. The chairman appealed to the public to help the committee by providing the sum still needed, so that the new buildings might be opened free from debt. The medical reports showed that the number of patients treated during the past year was 30,337, as compared with 28,274 in the preceding year. The total ordinary receipts for 1894 (exclusive of legacies) had been £5255 13s. 9d., against expenditure amounting to £9758 7s. 6d., the deficiency having been met partly by the legacies received and partly by encroaching upon the small reserve funds. The chairman strongly urged the claims of the charity upon the benevolent public, and stated that the small income derived from annual subscriptions was most inadequate, and he trusted that this would be augmented in the future. The committee of management, finance committee, treasurer, and auditors were duly elected, and a vote of thanks to the chairman closed the proceedings.

MEDICAL MAGISTRATES.—Dr. Alexander Macgregor of Aberdeen, and Dr. John Charles O. Will of the same city, have been placed on the Commission of the Peace for the county of Aberdeen.—Mr. Adam Wilkinson, M.D. Brux., F.R.C.S. Edin., &c., Shaftesbury, has been placed on the Commission of the Peace for the county of Dorset.

THE annual meeting of the East London Nursing Society will be held (by kind permission of the Lord Mayor) in the saloon at the Mansion House on Tuesday, March 12th, at 3 P.M. The chair will be taken by the Right Hon. the Lord Mayor, who will be supported by the Rev. Canon Elwyn (Master of the Charterhouse), Dr. Clement Godson, the Rev. J. F. Kitto (Vicar of St. Martin's, Charing-cross), the Rev. E. Hoskyns (Rector of Stepney), the Rev. F. Gurdon (Rector of Limehouse), and the Rev. Prebendary Harry Jones (Chairman of the Executive Committee).

MIDDLESEX HOSPITAL.—The annual meeting of the governors of the Middlesex Hospital was held on Feb. 28th, Mr. A. Pearce Gould presiding. The 150th yearly report was presented, and showed that the expenditure had exceeded the receipts by £1995. Sympathetic references were made to the death of Mr. J. W. Hulke, senior surgeon of the hospital, and President of the Royal College of Surgeons of England; the resignation of the chairman, Lord Sandhurst, in consequence of his important duties in India, was also a subject of regret, and his lordship was unanimously elected a vice-president. A new operating theatre has been built and will be completed in a few weeks.

WEST LONDON HOSPITAL.—The annual meeting of the governors of this hospital was held, on March 4th, at Hammersmith, Mr. W. Bird presiding. The thirty-eighth yearly report was presented, and made grateful mention of the Royal Charter of incorporation granted to the hospital last November. The extension of the hospital premises is making satisfactory progress, and when complete will enable eighty beds to be added to the present accommodation. The cost of these buildings is estimated at £20,000, of which £3500 have been already received. The expenditure for 1894 had exceeded the income, notwithstanding an increase of £39 in subscriptions, of £616 in donations, of £70 in the grant from the Metropolitan Hospital Sunday Fund, and of £740 in legacies.

ROYAL SURREY COUNTY HOSPITAL.—The Bishop of Winchester presided on Feb. 23rd at the annual court of governors of the Royal Surrey County Hospital, Guildford. Lord Middleton, the Hon. W. St. John Brodrick, M.P., Canon Haig-Brown, Headmaster of Charterhouse, Mr. E. J. Halsey, Chairman of the Surrey County Council, and the Mayors of Guildford and Godalming were also present. The annual report of the committee showed improvement in the financial position. The county meeting held at Guildford last October, under the presidency of H.R.H. the Duke of Connaught, with the object of obtaining £3300 to defray the expenses of new drainage and to build a new block for nurses, resulted in £1473 being raised, but before the building of the new block could be commenced a further sum of £1780 was required. Several subscriptions were announced at the meeting, among others £500 from a gentleman who remained anonymous and sent his donation through Mr. St. John Brodrick.

FOOTBALL CASUALTIES.—On the 23rd and 27th ult. and the 2nd inst. the following accidents occurred. While playing a match between the Aldershot Division and Blackheath a sergeant of the Royal Scots Greys fractured one of his legs, and was removed to the hospital.—During a match at East Acton between the Shepherd's Bush and Hammersmith Athletic Clubs, a player of the latter club fractured his leg and was taken to the West London Hospital.—A youth aged seventeen years, while playing a game on Southwark Park, fractured his right leg and was admitted to Guy's Hospital.—At Sunderland, in a match between Sunderland and Sheffield United teams, a player dislocated his humerus.—While playing a match at Cambridge for his College a player fractured his leg.—At Doncaster, during the Midland League match between the Doncaster Rovers and Kettering teams, one of the latter team "headed the ball while he had his tongue out of his mouth, and bit it so badly that it was nearly severed."—In the course of an English cup tie, for Middlesbrough against Darlington, a player sustained "a serious fracture of the hip-bone," and was conveyed to the North Riding Infirmary, Middlesbrough.—

During a game at Arundel a player fractured his leg, "the lower part of which was completely shattered and splintered." During a match at Hexham on Saturday last, between the Tynedale and Northern second teams, a player aged twenty-three years of the Tynedale team, received serious injuries, from which he died on the 5th inst.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Factories and Workshops Bill.

MR. TOMLINSON has given notice that when the Factories and Workshops Bill is read a second time he will move "that it be an instruction to the Committee that they have power to insert in the Bill provisions for extending its operation to post-offices and Government factories and workshops, and for prohibiting or restricting the importation into the United Kingdom of goods manufactured or treated in foreign countries otherwise than in accordance with the provisions of the Bill."

HOUSE OF COMMONS.

THURSDAY, FEB. 28TH.

The Drainage of the Tower of London.

Mr. Campbell-Bannerman, replying to a question, said that a thorough investigation of the drainage system of the Tower was completed last month, with the result that the system generally was not found to be defective. Some minor defects were found, and they were receiving attention.

THURSDAY, MARCH 7TH.

The Tuberculosis Committee.

Replying to a question put by Sir Matthew White Ridley, Mr. Shaw-Lefevre, President of the Local Government Board, said he trusted that the labours of this Committee might soon be concluded.

The Chicago Meat Factories.

In reply to Mr. Jeffreys, Mr. Herbert Gardner said he had read the article in the *Times* giving details concerning the preparation and packing of diseased meat at Chicago for export to England, and he proposed to make inquiry through the Foreign Office respecting it, and as to the arrangements in force in the United States for the prevention of the spread of disease. He should be very happy to bring under the notice of the President of the Local Government Board any information which might reach him as to the existence of danger to public health arising from the importation of diseased food products.

The Marking of Foreign Meat.

Mr. Jeffreys asked the President of the Board of Agriculture whether he was prepared to introduce a Bill for the purpose of registering dealers in foreign and colonial meat, and of inspecting retail butchers' shops under the Food and Drugs Act by duly qualified inspectors? Mr. Gardner called the attention of the hon. member to the amendment made last year in the Merchandise Marks Act, and said that the law as it now stood seemed to be sufficient to deal with the evil, and no further legislation was required.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- ADAMS, A. S., M.B., C.M. Aberd., has been appointed Parochial Medical Officer for the Parish of Alness.
- ALDRICH, A. W., L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer for the Worlington Sanitary District, and the Workhouse of the Mildenhall Union.
- ARNOLD, G. J., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.
- BARKING, H. GILBERT, M.B. Lond., B.S., F.R.C.S., has been appointed Honorary Consulting Surgeon to the Birmingham General Dispensary.
- BLACKER, A. BARRY, M.D., B.S. Durh., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Department for Diseases of the Throat at St. Thomas's Hospital.
- BOYD, JOHN J., M.B., C.M. Glasg., has been appointed House Surgeon to Grey's Hospital, Pietermaritzburg, Natal.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and House Surgeon for six months. Board and lodging provided.

Births, Marriages, and Deaths.

BIRTHS.

BARTER.—On Feb. 28th, at Manningtree, Essex, the wife of W. Whittington Baxter, M.R.C.S., of a son.

BRAND.—On Feb. 25th, at St. Paul's-road, Northampton, the wife of G. H. Brand, Surgeon, of a son.

BURNS.—On Feb. 19th, at Hamslade, Sweyn-road, Margate, the wife of Alfred Hugh Burns, L.R.C.P., L.S.A., of a son.

CASSIDY.—On Feb. 4th, at Purneah, Bengal, the wife of Surgeon-Captain C. Clemons Cassidy, Indian Medical Service, of a son.

FAWSETT.—On Feb. 25th, at High-street, Lewes, Sussex, the wife of Frank Fawcett, M.B., B.S. Lond., of a son.

FOX.—On March 3rd, at Brislington House, near Bristol, the wife of Bonville Bradley Fox, M.D., of a daughter.

HETLEY.—On March 5th, at Beaufort House, Church-road, Norwood, the wife of Dr. Henry Hetley, of a daughter.

PASSMORE.—On March 4th, at Tennyson House, Gainsborough, Lincs., the wife of John B. S. Passmore, M.R.C.S., L.R.C.P., of a son.

PHILLIPS.—On March 1st, at Grosvenor-street, W., the wife of John Phillips, M.A., M.D., F.R.C.P., of a son.

STURROCK.—On March 2nd, at Arima, Broughty Ferry, N.B., the wife of J. F. Sturrock, M.B., L.R.C.S.E., of a daughter.

THATCHER.—On Feb. 22th, at Melville-residence, Edinburgh, the wife of Charles H. Thatcher, F.R.C.S.E., of a daughter.

WILSON.—On Feb. 25th, at Goldhawk-road, Shepherd's Bush, London, W., the wife of Dr. James Wilson of a daughter.

MARRIAGES.

GREEN—HODGKINSON.—On Feb. 20th, at Holy Trinity Church, South Crosland, by the Rev. W. Le Neve Bower, Vicar, Thomas Arthur Green, M.B., C.M., eldest son of John Green, Heselaker, Skipton, to Selena, daughter of John Hodgkinson, Woodlands, Honley. At Home, Netherlerton, March 13th, 14th, 20th, and 21st.

DEATHS.

BROUGHTON.—On Feb. 26th, at Fyning, Guilford, James Wardlaw Broughton, M.D., aged 82.

CHANCE.—On Feb. 25th, at his residence, Russell-square, London, W.C., Edward John Chance, F.R.C.S. Eng., F.G.S., F.L.S., formerly of Old Broad-street, City, late Consulting Surgeon to the Metropolitan Hospital, Kingsland-road, N., and Senior Surgeon and Honorary Secretary to the City Orthopaedic Hospital, Hatton-garden, E.C., aged 88.

DE CRESPIGNY.—On Feb. 15th, at Crowcombe, Beckenham, Eric Champion de Crespiigny, M.D., of the Bombay Medical Service, aged 72.

GILCHRIST.—On Feb. 28th, at Alverstoke, Rochester, Surgeon-Major W. Gilchrist, M.D., late H.E.I.C.S., aged 88.

KING-PEIRCE.—On Feb. 27th, at Mentone, France, Richard King-Peirce, M.R.C.S., aged 72.

ROGERS.—On March 4th, at the Royal Naval Hospital, Stone-house, Edward Allan Rogers, Surgeon, R.N.

RUPP.—On Feb. 24th, at San Remo, Italy, Surgeon-Major General F. Rudd, M.D.

SATORY.—On March 4th, at Brook-street, W., Sir William Savory, Bart., F.R.S., in his 65th year.

SEMPLE.—On March 5th, Charles Edward Armand Semple, M.D., M.R.C.P. Lond., of Marlborough-hills, Harrow, and Torrington-square, London, W.C., aged 50.

TAKE.—On March 5th, at Welbeck-street, W., Daniel Hack Take, M.D., LL.D., F.R.C.P., aged 68, after a very short illness.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BELGRAVE HOSPITAL FOR CHILDREN.—House Surgeon. Board, lodging, fuel and light provided. Applications to honorary secretary at the hospital, 79, Gloucester-street, S.W.

CAMBERWELL HOUSE, 33, Peckham-road, Camberwell.—Assistant Medical Officer in a large Metropolitan asylum, unmarried. Salary to begin at £100 per annum, with board, lodging and washing. Applications to the Medical Superintendent to Camberwell House, 33, Peckham-road, Camberwell.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopedic (2 P.M.), City Orthopedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.). At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hector Mackenzie: A case of Hysterical Deafness successfully treated, with some Remarks on the Diagnosis and Treatment of this Affection.—Mr. Bruce Clarke: Thirty cases of Nephrorrhaphy, with their results.

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Adjourned Discussion on "Affections of the Nervous System occurring in the Early (Secondary) Stages of Syphilis," to be opened by Sir William Broadbent and Dr. Althaus.

WEDNESDAY.—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Discussion on "The Diagnosis and Treatment of Empyema of the Antrum of Highmore." (Members of the Odontological Society have been invited to take part.)

HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Mr. Hope Grant: Stricture of Oesophagus.—Dr. Fred. J. Smith: Cerebral Tumour.—Dr. Hingston Fox: Gall Stones.—Mr. Openshaw: (1) Gall Stone removed by operation from Ileum; (2) Congenital Sacral Tumour.

THURSDAY.—BRITISH GYNECOLOGICAL SOCIETY.—Specimen by Mr. Bowreman Jessett.—Dr. Macnaughton Jones: The Dangers of Morphia in Gynecological Practice.—Dr. Wm. Walter: Notes of a case of Leakage of a Multilocular Ovarian Cyst in a Girl aged thirteen.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—5 P.M. Dr. Waldo (Clifton): Notes of Cases. Exhibition of Patients, &c.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital).—8 P.M. Papers by Mr. Charles King, Dr. Christie, Dr. Burnett, and Mr. Macready.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Card Specimens by Messrs. S. Stephenson, A. Bronner, G. Hartridge, and Devereux Marshall. Papers.—Dr. G. Ogilvie: A case of Double Optic Atrophy with peculiar Visual Fields.—Dr. Argyll Robertson: A Female Filaria Loa.—Mr. Spencer Watson: A case of Foreign Body removed with a Traumatic Cataract.—Dr. Brailley: On a form of Iritis not usually recognised.—Mr. E. Treacher Collins: Blood-staining of the Cornea.

SOUTH WEST LONDON MEDICAL SOCIETY ("Stanley's," 235, Lavender-hill, Clapham-junct.).—8.30 P.M. Dr. Corfield: Foul Air and Disease.

FRIDAY.—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square).—8 P.M. Dr. Joseph Priestley: The Value of Eucalyptus Oil as a Disinfectant in Scarlet Fever.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. W. Lang: Iritis.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. Whistler: Syphilis as it affects the Larynx.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Prof. Charles Stewart: A Revision of the Endoskeleton in the Physiological Series in the Museum of the College.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Hyslop: Insanity with Cardiac Disease, Phthisis, Gout, &c.

ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals (IX.).

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. Arthur Newsholme: Natural History and Affinity of Rheumatic Fever. (Fourth Milroy Lecture.)

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Prof. Charles Stewart: A Revision of the Endoskeleton in the Physiological Series in the Museum of the College.

LONDON SKIN HOSPITAL.—8 P.M. Dr. Sanctuary: Eczema.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. S. Morton: Ocular Paralysis.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Impetigo and Contagious Suppuration.

SOCIETY OF ARTS.—8 P.M. Mr. E. Montague Nelson: The Meat Supply of the United Kingdom.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. A Discussion will be opened by Dr. James Niven on "Back-to-Back Houses, with Illustrations of various types of Back-to-Back Houses met with in practice, and the methods adopted for dealing with this class of property, by Mr. Thomas De Courcy Meade.

WEST LONDON HOSPITAL (Hammersmith, W.).—5 P.M. Dr. Turner: The Electrical Treatment of Nervous Diseases. (Post-graduate Course.)

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Mr. S. R. Gardiner: Three Periods of Seventeenth Century History.—II. The Commonwealth.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Mr. L. Hudson: Spinal Rotation Curvature.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Dr. Ormerod: The Gait in Various Forms of Paralysis.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. Barwell: Cases in the Wards.

SOCIETY OF ARTS.—4.30 P.M. Prof. Hubert Herkomer: Art Tuition.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. Arthur Newsholme: Natural History and Affinity of Rheumatic Fever. (Fourth Milroy Lecture.)

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Typhoid Fever and Diphtheria.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 P.M. Mr. W. H. Elam: Malignant Disease of the Thyroid.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Prof. Charles Stewart: A Revision of the Endoskeleton in the Physiological Series in the Museum of the College.

ROYAL INSTITUTION.—9 P.M. Prof. Roberts-Austen: The Rarer Metals and their Alloys.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Craig: Insanity with Syphilis; Insanity with Organic Brain Disease.

ROYAL INSTITUTION.—3 P.M. Lord Rayleigh: Waves and Vibrations (III.).

METEOROLOGICAL READINGS.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

BOOKS ABOUT MEDICINE.

To the Editors of THE LANCET.

SIRS,—In Cordy Jeaffreson's "Book about Doctors," in the chapter about fees, I find: "Dr. Doran, with his characteristic erudition, says, 'Now, there is a religious reason why fees are not supposed to be taken by physicians. Amongst the Christian martyrs are reckoned the two eastern brothers Damion and Cosmas,' &c. He goes on to say that they refused money, and were called "anargyri." I shall be much obliged if you or your readers can give me the title &c. of the work this is quoted from. I should also be glad to know what is the best modern general history of medicine in English. By this I mean a history

through all time and amongst all nations—not like Fort's Middle Ages or Wise's, the most modern I am acquainted with, but which is incorrectly entitled a "History of Medicine," as it deals merely with Asiatic developments. I do not want a translation. The only work I have at my disposal later than Hamilton is Meryon, but of this I have never been able to procure more than the first volume. Is any more published?

I am, Sirs, yours truly,

Paris, March 3rd, 1895.

ENQUIRER.

. The words are unfamiliar to us, but perhaps some of our readers may recognise them. They may possibly be found in Tuckerman's "Collector"—a series of essays upon, among other things, authors, medical men, divines, and actors, which was for a time edited by Dr. John Doran. The most recent general history of Medicine is a small but wide-ranging work by Dr. Edward F. Withington, entitled "Medical History from the Earliest Times." Dr. C. L. Meryon's book, "Memoirs of Lady Hester Stanhope, as related by herself in Conversations with her Physician," was originally published in three volumes, but we are uncertain if this is the work to which our correspondent refers.—ED. L.

"SAVE ME FROM MY FRIENDS."

To the Editors of THE LANCET.

SIRS,—Illness prevented me seeing your issue of the 23rd ult. for some days after its publication, and on perusal I found that you had copied a paragraph which appeared about me in the *Glasgow Evening News* some time ago. Had reference been made to the subject in question in the lay press I should probably have thought it better to let it pass unnoticed. Seeing, however, that it has found its way into the columns of a medical journal of such high standing and repute as THE LANCET I think it due to myself to make the following explanation. Briefly stated, the facts which gave rise to the paragraph are these. When delivering a lecture to the Glasgow Society of Musicians I was interrupted by a gentleman who desired me to proceed at once to meet my friend, Dr. Anderson Robertson, in consultation. Unfortunately, the gentleman—the father of the patient—in his excitement did not send in a message, but interrupted me while speaking, and under the awkward circumstances I requested permission of the audience to speak to him in the side-room. There I learned the facts of the case, and sent to three surgeons in the neighbourhood in the hope that I might find a substitute. No one could be got, and I was therefore compelled, seeing the case was one of urgency, to go myself. I operated in the usual way, injected antitoxin, and left the case in the hands of my friend. I heard nothing whatever about it for some time afterwards, when Dr. Anderson Robertson called to say that the child was making a very good recovery. In the interval, by some means or other, the facts had become known to the editor of the *Glasgow Evening News*, and the paragraph which you copied in THE LANCET was the result. I have to thank you for assuming without explanation, as you do in your footnote, that I would regret the appearance of the article in question, and that it was not my own doing. I was in no way responsible, directly or indirectly, for this paragraph. It appeared in the *Glasgow Evening News* nearly three months ago, and even at this moment I am quite unconscious of any channel by which the newspaper received information upon the subject. I am, Sirs, yours faithfully,

Glasgow, March 5th, 1895.

J. MACINTYRE.

. We print Dr. Macintyre's letter with pleasure and note with equal pleasure that he recognised that we knew him to be no party to the unfortunately worded paragraph.—ED. L.

CRIME AND ITS FACILITIES.

To the Editors of THE LANCET.

SIRS,—The following is an interesting history of fatality occurring in a family. Some months ago a man was admitted into this hospital having been impaled on a steel drill on which he had fallen in a sitting position. He died two days after admission. I give very briefly his family history:—1. Father stabbed and killed in a quarrel. 2. Mother some twenty years after was murdered on the same spot with a stab from a knife. 3. Brother stabbed in the chest, and died some years after from the effects of it. 4. Brother killed by accident in the mine. 5. Brother found dead in the country; cause unknown. 6. Brother died from chest affection. 7. One brother alive, but lame as result of accident. 8. A cousin committed suicide by shooting himself. 9. The mother, while a widow, had a sweetheart who was murdered.

I am, Sirs, yours faithfully,

ROBERT J. MARSHALL, M.B., C.M.

Hospital, Rio Tinto, Spain, Feb. 25th, 1895.

MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—I observe from a paragraph in THE LANCET dated Feb. 23rd, that the *Esculapian Lodge* has decided to entertain all medical masons that may attend the British Medical Association in August next. As one of the committee of the forthcoming meeting of the Association I look upon this masonic invitation as a most considerate, wise, and auspicious event. Let us as masons from all parts congregate together and strike a decisive blow which will tell the tale to the other members of our profession, and show them the firm basis, the true foundation, on which the order is built and the good fellowship that exists amongst us.

I am, Sirs, yours truly,

J. NOBLE BREDIN.

Martins, Boughton Monchelsea, Kent, Feb. 23rd, 1895.

THE CASE OF MR. C. BRYAN TOWNSHEND.

THE following subscriptions have been received or promised, and are hereby acknowledged with grateful thanks:—

Mr. Henry Morris (London) £5 5 0	Mr. Williams (Sherborne) £1 0 0
Dr. T. Buzzard (London) ... 5 5 0	Dr. H. Atwood (Beaver (Worcestershire) ... 1 0 0
Dr. Herbert R. Spencer (London) ... 2 2 0	Mr. W. Adams Frost (London) ... 1 1 0
Dr. Calthrop (London) ... 2 2 0	Dr. Turtle (Woodford) ... 1 1 0
Mr. F. Vacher (Birkenhead) ... 2 2 0	Dr. R. Hill (Western Hospital, Fulham) ... 0 10 0
Dr. Elliott (Bodmin) ... 1 0 0	

Further subscriptions are earnestly requested, and will be received and acknowledged by Rev. H. Townshend, 41, King Henry's-road, London, N.W.

F. V. D. is advised to apply to the deans of the schools of all the large hospitals. Bacteriological instruction is part of the curriculum at every school now, although the subject is not yet made compulsory in all examinations.

Mr. C. J. Lucas.—Only an experienced and skilled analyst and microscopist could undertake the inquiry, and even then the mode of preparation of the article, which is equally important, may defy discovery.

THE INFLUENZA EPIDEMIC.

To the Editors of THE LANCET.

SIRS,—I should be very much obliged if anyone could inform me whether in the present outbreak of influenza they have noticed that a great number of cases have presented very marked throat affections. A great number have lately come to me complaining of headache and pains in the back and limbs, often of a very severe character. On examining the throats in these cases I have found one or both tonsils to be frequently very enlarged and inflamed, and in many cases resembling somewhat a follicular tonsillitis. The uvula in nearly all cases has been markedly elongated, the soft palate highly inflamed, and the pharynx of a very dark red colour and usually dry. The tongue at first is coated with more or less greyish-white fur; but in twenty-four or forty-eight hours it has cleaned at the tip and edges, and presents a great many enlarged and prominent dark-red fungiform papillae, giving the tongue a strawberry appearance. The temperature for the first forty-eight hours or less ranges between 100° and 103° F. After this it generally quickly subsides to normal or subnormal, and the patient feels quite well, with the exception, however, now and then of rheumatic-like pains occurring in the back and limbs. The throat lesions, however, last from two to three weeks or more; but, curiously enough, in the majority of cases there is no pain on swallowing—in fact, the patient often does not complain of his throat at all, and inflammation there is only found on examination. Now and then there is a little pain and tenderness in the glands of the neck. In about one quarter of the cases there has been a rash, usually of a roseolous or erythematous character, sometimes, however, resembling urticaria. Its usual position is on the chest and arms, and often on the knees and outsides of the legs; it is of a very evanescent character as a rule. The chest may be a brilliant red at one time, and an hour or two later this redness may have quite disappeared, perhaps, however, to show itself on another part of the body. I have been so struck with the similarity of the throat and mouth affections &c. in so many cases that I should like to hear whether other observers have noticed the same signs &c.

I am, Sirs, yours faithfully,

JOHN TERRAT.

Guildford, March 4th, 1895.

"THE MEDICO-BOTANICO SOCIETY."

To the Editors of THE LANCET.

SIRS,—Your correspondent "Questor" will find an account of the "Royal Medico-Botanical Society" in Clarke's "Recollections of the Medical Profession," pp. 240, 267. He may also like to have his attention drawn to the notice of John Frost in the "Dictionary of National Biography."

I am, Sirs, yours truly,

March 4th, 1895.

JAS. B. BAILEY.

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent's question in your issue of March 2nd in reference to the Royal Medico-Botanical Society, there is a good account in Chapter 22 of the late Mr. J. F. Clarke's "Autobiographical Reminiscences of the Medical Profession," London, Churchill, 1874, and of Dr. Sigmund in the "Pettigrew's Medical Portrait Gallery," vol. iii., as well as in Forbes Winslow's "Physic and Physicians," vol. ii., London, second edition, Longmans, 1840.

I am, Sirs, yours faithfully,

D.A.P.

March 5th, 1895.

A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—Allow me to propose that there should be a gathering of the London and provincial octogenarians and upwards of the medical profession. Such a reunion would form an epoch in medical history. I would suggest a soirée, where we might agreeably discuss the past and present.

March 2nd, 1895.

I remain, Sirs, yours faithfully,

OCTOGENARIAN.

P.S.—I have been a reader of THE LANCET since 1836.

. We have much pleasure in printing our correspondent's suggestion: the nature and risks of their calling give to the octogenarian practitioners the right to be proud of their age. But if he desires to be a nonagenarian he had better not travel about to meetings until the weather is a little milder.—ED. L.

UNREASONABLE CHARGES AGAINST MEDICAL MEN.

THE *Western Mail* describes a very unseemly scene—or, as the coroner said, “a disgusting and disgraceful scene”—at an inquest at Cardiff on the body of Amelia Crago, aged thirteen. The mother of the child raged furiously at Dr. Milward for not going to see her child, and maintained that had he gone the child's life would have been saved. It was necessary finally to expel the woman from the court, when Dr. Milward explained his action to the satisfaction of the court. He advised at once, speaking from his bedroom through the tube, what should be done. In a few minutes he got a message of the death of the child. The jury found that the child had died from natural causes, and that no blame attached to him. The coroner was surprised at the violence of the attack on Dr. Milward, and said that in some of these cases there was no use in getting the people to give evidence until after the funeral. It is not necessary to judge too harshly a woman under poignant parental grief, especially when a coroner and jury combine to protect the medical man; but, all the same, it is hard on our profession to be so unjustly blamed.

Mr. Joseph W. Asprey.—A long report dealing exhaustively with this subject was published in THE LANCET of Nov. 25th, 1893, by THE LANCET Special Analytical Sanitary Commission. Copies of the reprint of this report may be had on application to the publisher.

F. D.—We regret to be unable to oblige our correspondent. It is a rule in our procedure from which we never depart that we do not recommend individual practitioners. But our correspondent's family medical man could give him the information he desires.

J. J. W.—We do not think there can be any objection taken to the proposal

“THE EXPLOITS OF A BONESETTER.”

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 23rd I see a letter concerning the “Exploits of a Bonesetter,” which has very much surprised me, because of the fact that it was written by a professional medical gentleman. What has been said concerning the “bonesetter” is, unfortunately, of frequent occurrence almost everywhere in the provinces, and as no good has ever come from our noticing such matters, or is ever likely to come from our doing so while the law acts so as to partially cover such practice, I should have thought that no medical man would have needed even the least hint as to his guidance on the points referred to by your correspondent, “Fair Play.” I fail to understand how there can be the slightest doubt in any reasonable brother's mind upon the matter of his “attitude” towards all “unqualified” persons presuming to practise medicine or surgery; but lest “Fair Play” has failed to appreciate fully his professional position and privileges, I would reply to his queries:—1. Adopt neither of the alternatives mentioned, which are unprofessional in every respect. 2. There is no law to “compel” any agricultural labourer or other individual to leave his ordinary avocation in life and “qualify” to practise medicine or surgery. Why should there be? Far too many of such enter our medical schools in order “to qualify” without any compulsion. 3. I shall leave this question to the General Medical Council to answer. Enough has been said by me to indicate my own personal opinion on this point.—I remain, Sirs, yours faithfully,
Feb. 26th, 1895.

S. W. W.

WANTED, A UNIVERSITY DEGREE.

To the Editors of THE LANCET.

SIRS,—Is there any university in the old country where a man who has been in practice ten years, holding double Royal English qualification, could obtain a degree upon passing a more or less purely practical examination? By way of Arts qualification the London University Matriculation Certificate is held.

I am, Sirs, your obedient servant,

Feb. 10th, 1895.

TRANSVAAL.

* No. The Students' Number of THE LANCET, published in the first week of every September, will give our correspondent full information on the subject, and he will there see exactly what facilities one or two universities offer.—ED. L.

THE JOURNAL OF COMPARATIVE PATHOLOGY AND THERAPEUTICS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me in what library I might hope to find a serial entitled “Journal of Comparative Pathology and Therapeutics”? It is not in the library of the Royal College of Surgeons of England or in that of the Royal Medical and Chirurgical Society. In what year did it first come out? I am, Sirs, yours truly,
Feb. 27th, 1895.

F.R.S.

WANTED A CONVALESCENT HOME FOR A SMALL-POX PATIENT.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a convalescent home where a small-pox patient would be received, and tell me at the same time the charges that would be incurred and the formalities that must be gone through?

March 5th, 1895.

I am, Sirs, yours faithfully,

A. N.

DEATH OF THREE OCTOGENARIAN BROTHERS.

THERE have just occurred, says the *Liverpool Daily Post*, at New Brighton three deaths which, by virtue of several circumstances, are worth more than a passing notice. Mr. Richard Owen Coulborn died on Saturday, the 23rd ult., in his eighty-third year. On the following Thursday his brother, Mr. Edward Warburton Coulborn, departed this life in his eighty-fifth year; and on the following Saturday a third brother, Mr. William Rushton Coulborn, was gathered to his fathers in his eighty-sixth year. All three brothers, who were the late owners of a ferry-boat service, lived and died in the same house, forming a remarkable example of a fact that is frequently seen—that where people have spent their lives together, in their death they are often not divided.

Inspector-General, R.N.—The success of the holders of the diplomas of the Conjoint Board of the Royal College of Physicians, London, and the Royal College of Surgeons of England has been made the subject of comment in our columns. Our correspondent's communication should, we think, have been signed.

W. H. H.—We cannot answer our correspondent's question; but his medical attendant would probably oblige him in the matter.

Temperance.—The Pasteurising process was inspected and examined by our Commissioners at 20, High Holborn, W.C.

Inquirer.—Finkler's papain was, we are informed, used in most, if not in every, case to which the paper refers.

CLINICAL INSTRUCTION FOR THE GRADUATE.

To the Editors of THE LANCET.

SIRS,—I beg to call your attention to a want which has been in existence for a great many years. After wandering about or resting in some isolated spot for ten or fifteen years, the zealous practitioner finds that it is desirable and often essential that he should return to his studies and regain some knowledge *in statu pupillari*. As an invariable result, however, such an individual will find himself regarded and tolerated as a sort of harmless lunatic. Such, at all events, has been the experience of myself and others who have endeavoured to take up work again. For instance, one man wished to go over the operations on the cadaver in order to give him some idea as to how the major operations are performed, another was seeking for instruction in the practical and theoretical subjects found in the examination for an M.D.'s degree, and again another required to work up for the Final M.B. Lond. I am quite sure that this want has only to be made known in order that provision may be made for men of maturer years, and thereby they may be able to profit to the fullest extent during the limited months or years which they may be able to set aside. Trusting that this letter may elicit some suggestions.

I remain, Sirs, yours faithfully,

March 4th, 1895.

1st M.B.

* The post-graduate lectures meet some of our correspondent's wants. For the rest his old hospital would surely welcome him back on payment of the usual fees, and it is hard to believe that either students or teachers would look upon his return to study as other than a very reasonable and praiseworthy course.—ED. L.

MRS. GUTHRIE RELIEF FUND.

To the Editors of THE LANCET.

SIRS,—I have to acknowledge with most sincere thanks the following donations and subscriptions:—

Sir Joseph Lister, Bart....	£10 0 0	Mr. C. J. Woollett ...	£1 1 0
Sir Jas. Paget ...	2 2 0	Rev. C. W. Bond, M.A.,	
Mr. R. J. Godlee* ...	1 1 0	St. Nicholas, Brighton	1 1 0
Mr. Stanley Boyd† ...	1 1 0	Mr. J. H. Morgan ...	1 1 0

* With a promise of £1 1s. each half-year if required.

† And £1 1s. each half-year during Mrs. Guthrie's lifetime.

I am, Sirs, your obedient servant,

March 6th, 1895.

M. R. BRANDRETH.
